Table of Contents

Introduction

1.1   Introducing the Zeus traffic management product family

Zeus traffic management products provide high-availability, application-centric traffic management and load balancing solutions. They provides control, intelligence, security and resilience for all your application traffic. These products are intended for organizations hosting valuable business-critical services, such as TCP and UDP-based services like HTTP (web) and media delivery, and XML-based services such as Web Services.

1.2   Introducing the Control API

A cluster of traffic mangers is normally managed using the web-based Admin Server on one of the machines.

Zeus's Control API provides an alternative means to remotely administer and configure a Zeus cluster. For example, when an Intrusion Detection System detects a remote attack attempt, it could use the Control API to configure the cluster to drop all connections from the suspect IP address.

A provisioning system could detect server overloading by monitoring the response times of the server nodes using Service Level Monitoring and the SNMP interface. Once it had provisioned additional servers, it could then reconfigure the server pools using the Zeus Control API.

1.2.1   Standards-conformant SOAP communications

The Control API is a standards-conformant SOAP-based API that provides the means for other applications to query and modify the configuration of the cluster.

> *SOAP is a lightweight protocol for exchange of information in a decentralized, distributed environment. It is an XML based protocol that consists of three parts: an envelope that defines a framework for describing what is in a message and how to process it, a set of encoding rules for expressing instances of application-defined datatypes, and a convention for representing remote procedure calls and responses.*

Simple Object Access Protocol (SOAP), w3.org

Most importantly, SOAP is a commonly accepted standard that allows applications to communicate. Zeus's Control API is published in the form of WSDL (Web Services Description Language) files. These files document which methods (remote procedure calls) are available, what input parameters they take and the output they return.

The WSDL files are located in `ZEUSHOME/zxtm/etc/wsdl`, and can be downloaded from the SOAP API page in the online help.

A SOAP-compliant programming environment will parse the WSDL files to determine which remote methods can be called, and will then allow the application to call these methods

much as if they were local functions. The SOAP environment insulates the application developer from the underlying complexity – network connectivity, XML formatting, cross-platform compatibility, etc. The application developer can concentrate on implementing the control logic required to support the application they are building.

The Zeus Control API can be used by any programming language and application environment that supports SOAP services. C#, Perl, Java and Python are commonly used.

1.3   SOAP-based Architecture
Fig. 1.   Arrangement of Management Server, Zeus Cluster and Server Nodes

A management application can issue a SOAP request to one of the traffic managers in a Zeus cluster. The application may be running on a stand-alone management server, one of the server nodes, or even on one of the traffic managers.

The application can issue the request to any of the Zeus traffic managers. The traffic managers automatically synchronize their configuration, so a configuration change sent to one machine is automatically replicated across the cluster.

1.3.1   Security Considerations

The SOAP-based management application communicates with a SOAP server running on the Zeus Admin Server, so the same security considerations apply:

- If a management network or IP-based access control is in use to secure the Admin Server, these will affect the locations that the management application can run from.

- SOAP traffic is automatically encrypted using SSL.

- The Zeus Admin Server will authenticate itself with its SSL certificate, which is generally self-signed.

  You may need to ensure that your SOAP application accepts self-signed certificates, or install a trusted SSL certificate in your Zeus admin server.

- SOAP requests are authenticated using the credentials of a users who is a member of a group with 'Control API' permissions in the Administration Server. Groups are defined in the Zeus Administration Interface, in the **System** > **Users** > **Groups** page.

  By default, the 'admin' group (which includes the user named 'admin') is the only group that is permitted to use the Zeus Control API. You can add this permission to other groups as required.

  You may wish to define a specific username for your management application to use, so that you can track its activity using traffic manager's Audit Log.

Code samples

The following code samples demonstrate how to call the Zeus Control API from several different application environments. They are intended to illustrate the similarities, rather than the best practice for each language.

2.1   Listing running virtual servers

The examples connect to a traffic manager, retrieve a list of the virtual servers and then query whether each virtual server is enabled (i.e. running). They then print out the running virtual servers.

The code structure is as follows:

- Specify the location of the admin server, and the username and password of an account in the 'admin' group or another group with explicit 'Zeus Control API' permissions (see section 1.3.1).

- If necessary, configure the HTTPS layer to accept the Admin Server's self-signed certificate.

- Instantiate a means of calling the SOAP methods of the **latest version** of the VirtualServer interface, generally with reference to the WSDL specification[1].

- Invoke the `VirtualServer:getVirtualServerNames()` method, which returns an array of string values.

- Invoke the `VirtualServer:getEnabled()` method, providing an array of string values (the names) and obtaining an array of Boolean values.

- Iterate through the arrays, printing the names of the virtual servers which are enabled.

2.1.1   listVS.pl using Perl SOAP::Lite

```perl
#!/usr/bin/perl -w

use SOAP::Lite 0.60;

# This is the url of the Zeus admin server
my $admin_server = 'https://username:password@host:9090';

my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap");
```

[1] Some environments, such as Perl's SOAP::Lite do not validate method calls against the WSDL specification.

```
# Get a list of virtual servers
my $res = $conn->getVirtualServerNames();
my @names = @{$res->result};

# Establish which are enabled
$res = $conn->getEnabled( \@names );
my @enabled = @{$res->result};

# Print those which are enabled
for( my $i = 0; $i <= $#names; $i++ ) {
    if( $enabled[$i] ) {
        print "$names[$i]\n";
    }
}
```

Run the example as follows:

```
$ ./listVS.pl
Main website
Mail servers
Test site
```

To run this example, you will need Perl, `SOAP::Lite` and `IO::Socket::SSL`.

- On Debian-based systems, install the packages `libsoap-lite-perl` and `libio-socket-ssl-perl`.
- On RedHat based systems, you'll need the `perl-SOAP-Lite` and `perl-IO-Socket-SSL` rpms
- Sites that use CPAN can obtain the modules from http://search.cpan.org/~byrne/SOAP-Lite-0.67/lib/OldDocs/SOAP/Lite.pm and http://search.cpan.org/~behroozi/IO-Socket-SSL-0.97/SSL.pm

Early versions of SOAP::Lite used a 'uri' method instead of the current 'ns' one. This affected versions prior to 0.65_5. If you are using a old SOAP::Lite, use the following code to create the SOAP::Lite connection instead:

```
my $conn = SOAP::Lite
    -> uri('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap");
```

Perl's `SOAP::Lite` module does not use the WSDL file to perform any type checking, so calling errors will be detected at runtime and SOAP structures and enumerations must be managed manually (see chapter 3). The SSL layer is happy to accept self-signed certificates.

2.1.2 listVS.cs using C Sharp

```csharp
using System;
using System.Net;
using System.IO;
using System.Security.Cryptography.X509Certificates;

public class AllowSelfSignedCerts : IcertificatePolicy {
   public bool CheckValidationResult(  ServicePoint sp,
        X509Certificate cert, WebRequest request, int problem )
   {
      return true;
   }
}

public class listVS {

   public static void Main( string [] args )
   {
      System.Net.ServicePointManager.CertificatePolicy =
         new AllowSelfSignedCerts();

      string url= "https://host:9090/soap";
      string username = "username";
      string password = "password";

      try {
         Zeus.VirtualServer p = new Zeus.VirtualServer();
         p.Url = url;
         p.Credentials = new NetworkCredential( username, password );

         string[] names = p.getVirtualServerNames();
         bool[] enabled = p.getEnabled( names );

         for ( int i = 0; i < names.Length; i++  ) {
            if( enabled[i] ) {
               Console.WriteLine( "{0}", names[i] );
            }
         }
      } catch ( Exception e ) {
         Console.WriteLine( "{0}", e );
      }
   }
}
```

This code works with the .NET 1.1 SDK and with Mono[2].

Using .Net 1.1, compile and run this example as follows:

```
C:\> wsdl -o:VirtualServer.cs -n:Zeus VirtualServer.wsdl
C:\> csc /out:listVS.exe VirtualServer.cs listVS.cs
C:\> listVS.exe
Main website
Mail servers
Test site
```

With Mono, compile and run as follows:

```
$ wsdl -o:VirtualServer.cs -n:Zeus VirtualServer.wsdl
$ mcs /out:listVS.exe /r:System.Web.Services \
        VirtualServer.cs listVS.cs
$ listVS.exe
Main website
Mail servers
Test site
```

The WSDL interface specifications for the Zeus Control API are located in ZEUSHOME/zxtm/etc/wsdl/, and can be downloaded from the SOAP API page in the online help.

Note the use of the IcertificatePolicy derived class to override the default certificate checking method. This allows the application to accept the Zeus Admin Server's self-signed certificate.

---

[2] Use the most recent build of Mono from http://www.mono-project.com/.

2.1.3 listVS.java using Java

```java
import com.zeus.soap.zxtm._1_0.*;

import java.security.Security;
import java.security.KeyStore;
import java.security.Provider;
import java.security.cert.X509Certificate;
import javax.net.ssl.ManagerFactoryParameters;
import javax.net.ssl.TrustManager;
import javax.net.ssl.TrustManagerFactorySpi;
import javax.net.ssl.X509TrustManager;

public class listVS {

   public static void main( String[] args ) {

      // Install the all-trusting trust manager
      Security.addProvider( new MyProvider() );
      Security.setProperty( "ssl.TrustManagerFactory.algorithm",
         "TrustAllCertificates" );

      try {
         VirtualServerLocator vsl = new VirtualServerLocator();
         vsl.setVirtualServerPortEndpointAddress(
            "https://username:password@host:9090/soap" );
         VirtualServerPort vsp = vsl.getVirtualServerPort();

         String[] vsnames = vsp.getVirtualServerNames();
         boolean[] vsenabled = vsp.getEnabled( vsnames );

         for( int i = 0; i < vsnames.length; i++ ){
            if( vsenabled[i] ){
               System.out.println( vsnames[i] );
            }
         }
      } catch (Exception e) {
         System.out.println( e.toString() );
      }

   }

   /* The following code disables certificate checking.
    * Use the Security.addProvider and Security.setProperty
```

```
     * calls to enable it */
   public static class MyProvider extends Provider {
      public MyProvider() {
         super( "MyProvider", 1.0, "Trust certificates" );
         put( "TrustManagerFactory.TrustAllCertificates",
            MyTrustManagerFactory.class.getName() );
      }

      protected static class MyTrustManagerFactory
            extends TrustManagerFactorySpi {
         public MyTrustManagerFactory() {}
         protected void engineInit( KeyStore keystore ) {}
         protected void engineInit(
            ManagerFactoryParameters mgrparams ) {}
         protected TrustManager[] engineGetTrustManagers() {
            return new TrustManager[] {
               new MyX509TrustManager()
            };
         }
      }

      protected static class MyX509TrustManager
            implements X509TrustManager {
         public void checkClientTrusted(
            X509Certificate[] chain, String authType) {}
         public void checkServerTrusted(
            X509Certificate[] chain, String authType) {}
         public X509Certificate[] getAcceptedIssuers() {
            return null;
         }
      }
   }
}
```

The bulk of this code disables client certificate checking. Details of the code and surrounding infrastructure are at:

http://java.sun.com/j2se/1.5.0/docs/guide/security/jsse/JSSERefGuide.html

This code works with the Java 1.5 SDK/JRE. To build and run the code, you'll need to do the following:

1. Download axis from http://ws.apache.org/axis/. This provides the WSDL-to-Java converter. Copy all the .jar files from `axis-<version>/libs/` to the `JAVAHOME`/jre/lib/ext/ directory, or add them to your `CLASSPATH`.

2. Install the Java Activation Framework and JavaMail libraries to avoid warnings when the code is run:

   o Java Activation Framework

      http://java.sun.com/products/javabeans/glasgow/jaf.html

   o JavaMail

      http://java.sun.com/products/javamail/

   Copy the `activation.jar` and `mail.jar` files contained in these packages to the `JAVAHOME`/jre/lib/ext/ directory, or add them to your `CLASSPATH`.

3. In your build directory, convert the required WSDL files into java code as follows[3]:

```
$ java org.apache.axis.wsdl.WSDL2Java VirtualServer.wsdl
```

4. Compile and run the example as follows:

```
$ javac listVS.java
$ java listVS
Main website
Mail servers
Test site
```

This code uses the functions within the VirtualServer interface. Other interfaces use a similar pattern.

For example, if you wished to access functions within the `XXX` interface, you would need to instantiate an `XXXLocator` object, declare the location of the traffic manager using the `setXXXPortEndpointAddress()` function and then create a connection using `getXXXPort()` to return an `XXXPort` object. You can then invoke methods using the `XXXPort` object. Java is verbose, but generally repetitive so the patterns can be copied thus:

```
SystemCacheLocator scl = new SystemCacheLocator();
scl.setSystemCachePortEndpointAddress(
    "https://username:password@host:9090/soap" );
SystemCachePort scp = scl.getSystemCachePort();
```

---

[3] The WSDL interface specifications for the Zeus Control API are located in `ZEUSHOME/zxtm/etc/wsdl/`.

```
/* Invoke the methods on the SystemCachePort object */
scp.clearWebCache();
```

2.1.4 listVS.py using Python

```
#!/usr/bin/python

import SOAPpy

conn = SOAPpy.WSDL.Proxy("VirtualServer.wsdl")
names = conn.getVirtualServerNames()
enabled = conn.getEnabled(names)

for i in range(0,len(names)):
        if ( enabled[i] ):
                print names[i]
```

By default, most SOAP implementations read the location of the SOAP server from the WSDL file[4]. However, for security reasons, the location of the Zeus Admin Server (including the required administrator username and password) is not embedded in the Zeus WSDL files.

Most SOAP toolkits allow you to override the location specified in the WSDL file, but Python's SOAP.py module does not. Before you run this example, edit your WSDL files. Look for the soap:address node at the very end of each WSDL file and edit appropriately:

```
<service name="VirtualServer">
   <port name="VirtualServerPort"
        binding="zeusns:VirtualServerBinding">
     <soap:address
        location="https://username:password@host:9090/soap" />
   </port>
</service>
```

Run the Python script as follows[5]:

> $ **./listVS.py**

---

[4] The WSDL interface specifications for the Zeus Control API are located in `ZEUSHOME/zxtm/etc/wsdl/`.

[5] This example was tested with Python 2.3.5 and version 0.11.5 of the SOAP.py library. Earlier versions of SOAP.py (0.8.4) could not correctly parse the WSDL file.

```
Main website
Mail servers
Test site
```

2.1.5 listVS.php using PHP 5

```php
#!/usr/bin/php5

<?
$conn = new SoapClient( "VirtualServer.wsdl",
    array('login' => "username", 'password' => "password") );

$names = $conn->getVirtualServerNames();
$enabled = $conn->getEnabled($names);

for ($i=0; $i < count( $names ); $i++) {
  if ( $enabled[$i] )
    print "$names[$i]\n";
}
?>
```

You may need to enable the SOAP extensions in your `php.ini` file; follow the instructions at http://www.php.net/soap if necessary.

Like Python, the PHP Soap toolkit expects to find the location of the SOAP server in the WSDL file, and does not provide any means to override it. However, you can specify the login details from your application, so these do not need to be embedded in the WSDL:

```xml
<service name="VirtualServer">
   <port name="VirtualServerPort"
         binding="zeusns:VirtualServerBinding">
      <soap:address location="https://host:9090/soap" />
   </port>
</service>
```

Run the PHP script as follows

```
$ ./listVS.php
Main website
Mail servers
Test site
```

2.2 Fault Handling

The Zeus Control API uses standard SOAP fault handling to inform the client application of errors. The type of fault returned depends on the error that occurred; for instance an 'ObjectDoesNotExist' fault will be returned when trying to set a property for a Virtual Server that doesn't exist. Information contained inside the fault will help determine more information about the error.

In addition to the specific faults specified for the functions, applications should be written to handle generic failures for which a specific fault does not exist.

Fault handling differs depending on the API being used. You should refer to your API documentation for details on how best to handle faults.

The following examples show code snippets of how to handle faults with various standard libraries.

2.2.1 Fault handling with SOAP::Lite

As SOAP::Lite doesn't read the WSDL files, the fault handling code needs to process the fault structures manually:

```
# This is the url of the Zeus admin server
my $admin_server = 'https://<user>:<pass>@adminserver:9090';

my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap")
    -> on_fault( \&handle_fault );

sub handle_fault
{
   my( $soap, $res ) = @_;

   if( ! $res ) die "A transport error occured\n";

   if( ! ref $res ) die $res;

   # $res is a SOAP fault - extract the information in it
   if( $res->faultdetail ) {
      my $detail = $res->faultdetail;
      my @elems = keys %$detail;
      my $fault = $elems[0];

      my $msg = "SOAP Fault: $fault\n";

      # Extract out the components of the fault
```

```
        foreach my $key( qw( errmsg object key value ) ) {
            if( defined $detail->{$fault}->{$key} ) {
                $msg .= "  $key: " . $detail->{$fault}->{$key} ."\n";
            }
        }
        die $msg;
    } else {
        die "SOAP Fault: " . $res->faultcode . ": " .
            $res->faultstring . "\n";
    }
}

# Could throw 'ObjectDoesNotExist'
$conn->setEnabled( [ "my-virtual-server" ], [ 1 ] );
```

2.2.2 Fault handling using C sharp

Like perl, the fault detail structure needs to be inspected manually:

```
try {
    p.setEnabled( new string[] { "my-virtual-server" },
                  new bool[] { true } );
} catch( SoapException fault ) {
    string msg = "";
    // Look at the fault detail XML tree
    if( fault.Detail != null && fault.Detail.FirstChild != null ) {
        XmlNode detail = fault.Detail.FirstChild;

        // The SOAP fault is the name of the first child of the
        // fault detail
        msg += "SOAP Fault: " + detail.LocalName + "\n";

        // And the other members of the fault are children
        XmlNodeList children = detail.ChildNodes;
        for( int i = 0 ; i < children.Count ; i++ ) {
            msg += "  " + children[i].Name + ": " +
                        children[i].InnerText + "\n";
        }
    } else {
        // Otherwise this is a generic fault - just print the fault
        msg = fault.ToString();
    }
    Console.Write( msg );
```

```
}
```

2.2.3 Fault handling using Java

Fault handling is built into the Java AXIS libraries; the SOAP faults are translated into standard Java exceptions which make it very easy to handle faults:

```
VirtualServerLocator vsl = new VirtualServerLocator();
vsl.setVirtualServerPortEndpointAddress(
      "https://<user>:<pass>@adminserver:9090/soap" );
VirtualServerPort vsp = vsl.getVirtualServerPort();

try {
   vsp.setEnabled( new String[] { "my-virtual-server" },
                   new boolean[] { true } );

   System.out.println( "Virtual Server enabled successfully" );
} catch( ObjectDoesNotExist e ) {
   System.err.println(
      "Virtual Server '" + e.getObject() + "' does not exist" );
} catch( RemoteException e ) {
   System.err.println( "Generic exception: " + e );
}
```

Using Perl SOAP::Lite

Unlike most other SOAP APIs, Perl's SOAP::Lite does not take regard of the WSDL specification for the Control API interface. Special measures must be taken to use the Control API accurately.

3.1 Control API methods

A method can be invoked from a SOAP::Lite connection object that specifies the appropriate interface:

```
# Create a connection object that uses the VirtualServer interface
my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap");

# You can invoke any of the methods of the VirtualServer interface
my $res = $conn->getVirtualServerNames();
```

If you need to use several interfaces (for example, VirtualServer and Pool), you will need to construct a SOAP::Lite connection object for each.

If you attempt to invoke a method that does not exist for the interface, the method call will fail and the `on_fault` fault handler (if specified) will be called.

Note that when a new version of Zeus Traffic Manager is released, individual interfaces might be changed in some way that alters their use or behavior. This could be in order to fix a bug or to provide additional functionality. If this situation occurs, instead of amending the existing interface, a new later version-numbered interface will be included with the release (which you should always try to use). However, previous versions are always preserved to ensure backwards compatibility with your existing applications. The interface version is identified in the `ns` string provided to the connection object, and the Function Reference contained in this document always refers to the latest version available.

3.2 Control API Enumerations

An Enumeration is a particular datatype with a restricted, named set of values. For example, a Pool has a limited set of load balancing algorithms that are represented by the `Pool.LoadBalancingAlgorithm` enumeration:

The enumeration is defined as follows:

Pool.LoadBalancingAlgorithm

```
enum Pool.LoadBalancingAlgorithm {
    roundrobin,      # Round Robin
    wroundrobin,     # Weighted Round Robin
    cells,           # Perceptive
    connections,     # Least Connections
    wconnections,    # Weighted Least Connections
    responsetimes,   # Fastest Response Time
    random           # Random node
}
```

The Pool interface contains two methods that use that enumeration:

getLoadBalancingAlgorithm(names)

Get the load balancing algorithms that each of the named pools uses.

```
Pool.LoadBalancingAlgorithm[] getLoadBalancingAlgorithm(
    String[] names
)
```

setLoadBalancingAlgorithm(names, values)

Set the load balancing algorithms that each of the named pools uses.

```
void setLoadBalancingAlgorithm(
    String[] names
    Pool.LoadBalancingAlgorithm[] values
)
```

Perl's SOAP::Lite library correctly encodes enumerations in SOAP requests, so you can use them in a literal fashion:

```
$conn->setLoadBalancingAlgorithm( [ $poolName ], ['connections'] );
```

In a SOAP response, you need to provide a custom Deserializer so that the SOAP::Lite library can convert the values in the SOAP response into appropriate internal representations (i.e. literal strings):

```
BEGIN {
    package MyDeserializer;
    @MyDeserializer::ISA = 'SOAP::Deserializer';

    sub typecast {
        my( $self, $val, $name, $attrs, $children, $type ) = @_;
        if( $type && $type =~ m@http://soap.zeus.com/zxtm/@ ) {
            return $val;
        }
```

```perl
        return undef;
    };
}

my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/Pool/')
    -> proxy("$admin_server/soap")
    -> deserializer( MyDeserializer->new );
```

The following code sample illustrates how to use Control API methods that use Enumerations:

```perl
#!/usr/bin/perl -w

use SOAP::Lite 0.6;

# Provide our own Deserializer to deserialize enums correctly
BEGIN {
    package MyDeserializer;
    @MyDeserializer::ISA = 'SOAP::Deserializer';

    sub typecast {
        my( $self, $val, $name, $attrs, $children, $type ) = @_;
        if( $type && $type =~ m@http://soap.zeus.com/zxtm/@ ) {
            return $val;
        }
        return undef;
    };
}

# This is the url of the Zeus admin server
my $admin_server = 'https://username:password@host:9090';

# The pool to edit
my $poolName = $ARGV[0] or die "No pool specified";

my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/Pool/')
    -> proxy("$admin_server/soap")
    -> deserializer( MyDeserializer->new )
    -> on_fault( sub  {
        my( $conn, $res ) = @_;
        die ref $res?$res->faultstring:$conn->transport->status; }
```

```
);

# Get the load balancing algorithm
my $res = $conn->getLoadBalancingAlgorithm( [ $poolName ] );
my $alg = @{$res->result}[0];
print "Pool $poolName uses load balancing algorithm $alg\n";

# Change the algorithm to least connections, and check it worked
$conn->setLoadBalancingAlgorithm( [ $poolName ], ['connections'] );
$res = $conn->getLoadBalancingAlgorithm( [ $poolName ] );
print "Algorithm has been changed to @{$res->result}[0]\n";

# Now change it back again
$conn->setLoadBalancingAlgorithm( [ $poolName ], [ $alg ] );
$res = $conn->getLoadBalancingAlgorithm( [ $poolName ] );
print "Algorithm changed back to @{$res->result}[0]\n";
```

3.3 Control API Structures

A Structure is a complex datatype that contains several parameters. For example, the key configuration settings for a Virtual Server are represented by a VirtualServer.BasicInfo structure that defines the port, protocol and default pool for that Virtual Server:

VirtualServer.BasicInfo

This structure contains the basic information for a virtual server. It is used when creating a server, or modifying the port, protocol or default pool of a server.

```
struct VirtualServer.BasicInfo {
    # The port to listen for incoming connections on.
    Integer port;

    # The protocol that this virtual server handles.
    VirtualServer.Protocol protocol;

    # The default pool that traffic to this virtual server will go
    # to.
    String default_pool;
}
```

This structure contains three elements; an Integer (the port number), an Enumeration (VirtualServer.Protocol – the protocol) and a string (the name of the default pool).

The method `VirtualServer.addVirtualServer()` takes a `VirtualServer.BasicInfo` structure which can be constructed as follows:

```perl
my $basicInfo = {
   port         => '443',
   protocol     => 'https',
   default_pool => 'Server Pool 1'
};

$res = $conn->addVirtualServer( [ $vsName ], [ $basicInfo ] );
```

If you call the method `VirtualServer.getBasicInfo()`, it will return a corresponding array of `VirtualServer.BasicInfo` structures that can be unpacked as follows:

```perl
$res = $conn->getBasicInfo( [ $vsName ] );
my $r = @{$res->result}[0];

print "Virtual Server $vsName:\n";
print "   port $r->{port}, protocol $r->{protocol}, " .
      "pool $r->{default_pool}\n";
```

The following code sample illustrates how to create a virtual server and manage the BasicInfo structure:

```perl
#!/usr/bin/perl -w

use SOAP::Lite 0.6;

# Provide our own Deserializer so to deserialize enums correctly
BEGIN {
   package MyDeserializer;
   @MyDeserializer::ISA = 'SOAP::Deserializer';

   sub typecast {
      my( $self, $val, $name, $attrs, $children, $type ) = @_;
      if( $type && $type =~ m@http://soap.zeus.com/zxtm/@) {
         return $val;
      }
      return undef;
   };
}

# This is the url of the Zeus admin server
```

```perl
my $admin_server = 'https://user:password@hostname:9090';

# The virtual server to create
my $vsName = $ARGV[0] or die "No vs specified";

my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap")
    -> deserializer( MyDeserializer->new )
    -> on_fault( sub  {
        my( $conn, $res ) = @_;
        die ref $res?$res->faultstring:$conn->transport->status; }
);

# Construct the basic info structure
my $basicInfo = {
    port         => '443',
    protocol     => 'https',
    default_pool => 'discard'
};

$res = $conn->addVirtualServer( [ $vsName ], [ $basicInfo ] );

$res = $conn->getBasicInfo( [ $vsName ] );
my $r = @{$res->result}[0];

print "Virtual Server $vsName:\n";
print "   port $r->{port}, protocol $r->{protocol}, " .
      "pool $r->{default_pool}\n";
```

Sample Control API applications

The Zeus Control API can perform almost any configuration task that can be accomplished using the Zeus Admin Server. Its strength comes from how it can be driven by other management applications elsewhere in the network.

4.1 Blocking traffic from an IP address

An Intrusion Detection System (IDS) or a live log analysis tool may identify remote hosts which are sending undesired traffic – malicious requests, port scans, or simply excessive numbers of requests in an attempt to mount a denial-of-service attack.

The IDS may be located behind the traffic manager cluster, for example, if it needs to inspect SSL traffic that has been decrypted by the traffic managers. In this case, the IDS can use the Control API to update the traffic manager cluster to prevent it from accepting any more traffic from the suspected IP address.

The following Zeus Control API application modifies a named Service Protection Policy, adding an IP address to the list of banned IP addresses. The Service Protection Policy should be assigned to the appropriate Virtual Servers managing traffic in the cluster.

4.1.1 Perl Example

```perl
#!/usr/bin/perl -w

use SOAP::Lite 0.60;

# This is the url of the Zeus admin server
my $admin_server = 'https://username:password@host:9090';

# The protection policy to edit, and the node to add
my $name = "My protection class";
my $badIP  = "10.100.1.10";

my $conn = SOAP::Lite
    -> uri('http://soap.zeus.com/zxtm/1.0/Catalog/Protection/')
    -> proxy("$admin_server/soap")
    -> on_fault( sub  {
        my( $conn, $res ) = @_;
        die ref $res ? $res->faultstring :
            $conn->transport->status; } );

$conn->addBannedAddresses( [ $name ], [ [ $badIP ] ] );
```

Notes

We are accessing the 'Catalog/Protection' uri to edit a service protection class. With a WSDL-based interface, we'd use the `Catalog.Protection.wsdl` interface.

We use the `addBannedAddresses()` function. Like most Control API functions, this takes a series of arrays as arguments:

1. A list of service protection policies

2. A list of lists of banned IP addresses

This means that the function can perform bulk updates, modifying several objects simultaneously.

This example includes a basic `on_fault` handler which is called if an error ever occurs. The handler will report a transport error if the SOAP application could not connect to the remote SOAP server. Otherwise, it will report a SOAP error.

For more a more sophisticated example of a Perl fault handler, refer to section 2.2.1.

4.1.2 C# Example

```csharp
using System;
using System.Net;
using System.IO;
using System.Security.Cryptography.X509Certificates;

public class AllowSelfSignedCerts : ICertificatePolicy {
   public bool CheckValidationResult(
         ServicePoint sp, X509Certificate cert,
         WebRequest request, int problem )
   { return true; }
}

public class addBannedAddress {

   public static void Main( string [] args )
   {
      System.Net.ServicePointManager.CertificatePolicy =
         new AllowSelfSignedCerts();

      string url= "https://host:9090/soap";
      string username = "username";
      string password = "password";

      string name = "My protection class";
      string badIP = "10.100.1.10";
```

```
    try {
        Zeus.CatalogProtection p =
                new Zeus.CatalogProtection();
        p.Url = url;
        p.Credentials = new NetworkCredential(
            username, password );

        p.addBannedAddresses( new string[] { name },
            new string[][] { new string[]{ badIP } } );
    } catch ( Exception e ) {
        Console.WriteLine( "{0}", e );
    }
  }
}
```

4.2   Adding a node to a pool

Provisioning systems can dynamically deploy applications across servers, perhaps in reaction to increased server load. This example demonstrates a Control API application that modifies the nodes that a pool balances traffic to.

If the pool is using the 'Perceptive' algorithm, then load will slowly be ramped up on newly introduced nodes, gauging their potential performance, until they run at the same speed as the other nodes in the pool. This 'Slow Start' capability ensures that new nodes are not immediately overloaded with a large burst of traffic.

4.2.1   Perl Example

```
#!/usr/bin/perl -w

use SOAP::Lite 0.60;

# This is the url of the Zeus admin server
my $admin_server = 'https://username:password@host:9090';

# The pool to edit, and the node to add
my $poolName = "test pool";
my $newNode  = "10.100.1.10:80";

my $conn = SOAP::Lite
    -> uri('http://soap.zeus.com/zxtm/1.0/Pool/')
    -> proxy("$admin_server/soap")
    -> on_fault( sub  {
```

```perl
        my( $conn, $res ) = @_;
        die ref $res ? $res->faultstring :
            $conn->transport->status; } );

# Get a list of pools
my $res = $conn->getPoolNames();
my @names = @{$res->result};

# Get the nodes for each pool
$res = $conn->getNodes( \@names );

# Build a hash %nodes: pool->[ node list ]
my %nodes;
@nodes{@names} = @{$res->result};

if( !defined $nodes{$poolName} ) {
    die "Pool $poolName does not exist...";
}

if( grep { $_ eq $newNode } @{$nodes{$poolName}} ) {
    die "Pool $poolName already contains $newNode";
}

# Add one node to the pool
$res = $conn->addNodes( [ $poolName ], [ [ $newNode ] ] );

# We're done!  Verify that the node has been added
$res = $conn->getNodes( [ $poolName ] );
my @newnodes = @{${$res->result}[0]};

my $expected = join " ",
    sort @{$nodes{$poolName}}, $newNode;
my $actual   = join " ", sort @newnodes;

if( $expected ne $actual ) {
    die "New node list is '$actual'; expected '$expected'";
}
```

Notes

This example uses careful error checking to make sure that the Control API methods are not called incorrectly. For example, if a method tries to add a node to a pool that did not exist, a SOAP fault will be raised. Perl's `on_fault` handler will be called if this happens.

The example illustrates Perl's hash slice technique to quickly build an associative array, mapping pool name to a list of nodes:

```
my $res = $conn->getPoolNames();
my @names = @{$res->result};
$res = $conn->getNodes( \@names );
my %nodes;
@nodes{@names} = @{$res->result};
```

This is a very easy way to take advantage of the fact that the Zeus Control API methods are all bulk-enabled, i.e., they are designed to process lists of objects efficiently.

The listVS example could also use a hash slice, as follows:

```
my $res = $conn->getVirtualServerNames();
my @names = @{$res->result};
$res = $conn->getEnabled( \@names );
my %enabled;
@enabled{@names} = @{$res->result};
```

A Zeus Control API application could update the configuration by modifying the hash:

```
# Turn everything off...
foreach my $name( keys %enabled ) {
   $enabled{ $name } = 0;
}
```

It could then bulk-commit the new configuration with a single method call:

```
$res = $conn->setEnabled(
            [ keys %enabled ], [ values %enabled ] );
```

4.2.2 C# Example

```csharp
using System;
using System.Net;
using System.IO;
using System.Security.Cryptography.X509Certificates;

public class AllowSelfSignedCerts : ICertificatePolicy {
    public bool CheckValidationResult(
            ServicePoint sp, X509Certificate cert,
            WebRequest request, int problem )
    {
        return true;
    }
}
public class addNode {
    public static void Main( string [] args )
    {
        System.Net.ServicePointManager.CertificatePolicy =
            new AllowSelfSignedCerts();

        string url= "https://host:9090/soap";
        string username = "username";
        string password = "password";

        string poolName = "test pool";
        string newNode  = "10.100.1.10:80";

        try {
            Zeus.Pool p = new Zeus.Pool();
            p.Url = url;
            p.Credentials = new NetworkCredential(
                username, password );

            string[] names = p.getPoolNames();
            string[][] allnodes = p.getNodes( names );

            string[] nodes = new string[]{};
            bool found = false;
            for( int i = 0 ; i < names.Length ; i++ ) {

                if( names[i] == poolName ) {
                    nodes = allnodes[i];
                    found = true;
```

```
                break;
            }
        }

        if( ! found ) {
            Console.WriteLine( "Pool {0} doesn't exist", poolName );
            Environment.Exit( 1 );
        }

        found = false;
        for( int i = 0 ; i < nodes.Length ; i++ ) {
            if( nodes[i] == newNode ) {
                found = true;
            }
        }
        if( found ) {
            Console.WriteLine( "Pool {0} already contains {1}",
                poolName, newNode );
            Environment.Exit( 1 );
        }

        // Add one node to the pool
        p.addNodes( new string[] { poolName },
            new string[][] { new string[] { newNode } } );

    } catch ( Exception e ) {
        Console.WriteLine( "{0}", e );
    }
  }
}
```

4.3 Reconfiguring your site based on Traffic Load

In this example, we'll monitor the performance of the JSP pages on a website. If the performance drops below an acceptable level, we'll use the Control API to enable a TrafficScript rule that prevents more users from logging into the website. Once performance climbs back to an acceptable level, the Control API application can disable the rule.

The TrafficScript Rule

To prevent users from logging into the site, we could use a TrafficScript rule similar to the following:

```
$path = http.getPath();
if( string.endsWith( $path, "login.jsp" ) ) {
   http.redirect( "/content/login_disabled.html" );
}
```

Add this rule to the Rules catalog, calling it 'Disable Login'. Configure it as a request rule for your virtual server, but set it to be disabled. The Zeus Control API application will use the Virtual Server `getRules`() and `setRules`() functions to modify the 'enabled' status of the rule.

Monitoring Performance

Performance of the web application can be monitored in a variety of ways:

- Using statistics gathered from the web application itself.

- Using an external monitoring tool to send probe requests.

- Monitoring the node response times using SNMP and the Service Level Monitoring capability.

- Using the SNMP or email alerts raised by Service Level Monitoring to drive the Control API applications directly.

Enabling and Disabling the Rule

The following Control API code retrieves the list of response rules that the named virtual server is using. It searches for the rule named 'Disable Login' and enables it. If the rule is not present, it adds it as the first rule to be executed.

4.3.1 Perl example

```
#!/usr/bin/perl -w

use SOAP::Lite 0.60;

# Provide our own Deserializer so to deserialize enums correctly
BEGIN {
   package MyDeserializer;
   @MyDeserializer::ISA = 'SOAP::Deserializer';

   sub typecast {
      my( $self, $val, $name, $attrs, $children, $type ) = @_;
```

```perl
        if( $type && $type =~ m@http://soap.zeus.com/zxtm/@) {
            return $val;
        }
        return undef;
    };
}

# This is the url of the Zeus admin server
my $admin_server = 'https://username:password@host:9090';

# The virtual server to edit, and the rule to enable
my $vsName = "Main web site";
my $rule   = "Disable Login";

my $conn = SOAP::Lite
    -> uri('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap")
    -> deserializer( MyDeserializer->new )
    -> on_fault( sub  {
       my( $conn, $res ) = @_;
       die ref $res ? $res->faultstring:conn->transport->status; } );

# Get a list of rules used by the named virtual server
my $res = $conn->getRules( [ $vsName ] );
my @rules = @{${$res->result}[0]};

my $found = 0;
foreach my $f ( @rules ) {
    if( $f->{name} eq $rule ) {
        $f->{enabled} = 1; $found = 1; last;
    }
}
if( !$found ) {
    # Add a new rule to the start of the list
    unshift @rules, {
        name => $rule,
        enabled => 1,
        run_frequency => 'only_first'
    };
}

$res = $conn->setRules( [ $vsName ], [ [ @rules ] ] );
```

Notes

The rules manipulation functions take a compound `VirtualServer.Rule` structure which uses an enumeration named '`RuleRunFlag`'.

The `SOAP::Lite` interface presents this structure as a standard Perl hash, requiring a Deserializer to manage the enumeration.

C# presents it as an object of type `Zeus.VirtualServerRule` containing an enumeration of type `Zeus.VirtualServerRuleRunFlag`.

4.3.2 C# Example

```
using System;
using System.Net;
using System.IO;
using System.Security.Cryptography.X509Certificates;

public class AllowSelfSignedCerts : ICertificatePolicy {
   public bool CheckValidationResult(
         ServicePoint sp, X509Certificate cert,
         WebRequest request, int problem )
   {
      return true;
   }
}

public class addNode {
   public static void Main( string [] args )
   {
      System.Net.ServicePointManager.CertificatePolicy =
         new AllowSelfSignedCerts();

      string url= "https://host:9090/soap";
      string username = "username";
      string password = "password";

      string vsName  = "Main web site";
      string rule    = "Disable login";
      try {
         Zeus.VirtualServer p = new Zeus.VirtualServer();
         p.Url = url;
         p.Credentials = new NetworkCredential(
            username, password );

         // Get a list of rules used by the named
```

```
        // virtual server
        Zeus.VirtualServerRule[][] rules =
            p.getRules( new string[] { vsName } );

        // Search for the rule to enable
        bool found = false;
        foreach( Zeus.VirtualServerRule r in rules[0] ) {
            if( r.name == rule ) {
                found = true; r.enabled = true;
            }
        }
        if( ! found ) {
            // Add a new rule to the start of the list
            Zeus.VirtualServerRule[] newrules = new
                Zeus.VirtualServerRule[rules[0].Length + 1];
            newrules[0] = new Zeus.VirtualServerRule();
            newrules[0].name = rule;
            newrules[0].enabled = true;
            newrules[0].run_frequency =
                Zeus.VirtualServerRuleRunFlag.only_first;

            Array.Copy( rules[0], 0, newrules, 1, rules[0].Length );

            rules[0] = newrules;
        }
        p.setRules( new string[] { vsName }, rules );

    } catch ( Exception e ) {
        Console.WriteLine( "{0}", e );
    }
  }
}
```

Troubleshooting

5.1   Overview

Building Zeus Control API applications is an involved process. This chapter lists some useful techniques.

5.1.1 Can't find the WSDL files?

The WSDL interface specifications are located in:

        ZEUSHOME/zxtm/etc/wsdl/

ZEUSHOME is the installation directory for your Zeus software, typically /usr/local/zeus/.

You can also download them from the SOAP API page in the online help.

5.2   General Debugging Techniques

5.2.1 Log Files

In the event of a problem, review the following error logs:

- Zeus Software: ZEUSHOME/log/errors

    Validation errors and incorrect configuration problems will be reported in this log file.

- Zeus Admin Server: ZEUSHOME/admin/log/errors

    The Admin Server processes the SOAP requests and sends the new configuration to the Zeus software. Any SOAP protocol or transport errors will be reported here.

5.2.2 Snooping the SOAP traffic

Your Zeus Control API application will send SOAP requests to the Zeus Admin server, which typically listens using SSL on port 9090. If your SOAP toolkit does not support debugging or tracing, you can use a network snooping tool such as WireShark[6] to inspect the SOAP request and response, to verify that the request is sent correctly, and that the response does not contain any errors messages that are not reported by your application's interface code.

Of course, if your SOAP transaction is encrypted with SSL, it will not be easy to inspect it:

1. Disable SSL on the Zeus Admin Server as follows:

---

[6] http://www.wireshark.org/   WireShark is available for all major platforms, including Windows, Linux and Mac OS X.

a. Edit the file `ZEUSHOME/admin/website`, and comment out the line 'security!enabled yes' by prefixing it with a '#':

```
#security!enabled yes
```

b. Restart the software[7]:

```
# /usr/local/zeus/restart-zeus
```

2. Modify your Zeus Control API application to use an 'http://' url rather than an 'https://' one.

5.3   Debugging with Perl

5.3.1   Problems with WSDL interfaces

Because Perl's SOAP::Lite does not make explicit reference to the WSDL interface specification, it can be easy to make errors which are only detected at run time.

Ensure that the URI in the SOAP::Lite objects you construct in your application is correct. Refer to the URI tables in chapter 6.

For example, to reference methods in the VirtualServer interface, you should use the following URI:

```
http://soap.zeus.com/zxtm/1.0/VirtualServer/
```

For methods in the Service Protection catalog, use the following URI:

http://soap.zeus.com/zxtm/1.0/Catalogs/Protection/

5.3.2   Using a Fault Handler

Your Perl SOAP::Lite client application can determine whether server or transport errors have occurred by inspecting the SOAP Fault that is raised on an error.

Section 2.2 covers Fault Handlers in detail.

---

[7] Alternatively, you can restart just the admin server component as follows:
    # **export ZEUSHOME=/usr/local/zeus**
    # **$ZEUSHOME/admin/rc restart**
Set ZEUSHOME to the correct installation directory for your configuration.

5.3.3 Recent SOAP::Lite versions

Versions of SOAP::Lite on or after 0.65_5 have a slightly different interface. When creating a SOAP::Lite connection, you should use a new 'ns' method instead of the previous 'uri' method:

```
# Versions prior to 0.65_5
my $conn = SOAP::Lite
    -> uri('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap");
```

```
# Versions 0.65_5 and later
my $conn = SOAP::Lite
    -> ns('http://soap.zeus.com/zxtm/1.0/VirtualServer/')
    -> proxy("$admin_server/soap");
```

5.3.4 Perl deserializer Example

The SOAP::Lite module does not make use of Zeus's WSDL specification and so does not know how to deserialize some enumerations used. See chapter 3 for an example of this problem.

5.3.5 Tracing

When you import the SOAP::Lite module, use the following:

```
use SOAP::Lite 0.6 +trace => 'debug';
```

This will cause the SOAP::Lite module to output large amounts of debugging information.

The XML-messages you see after enabling the tracing are usually not formatted. To make them easier to read, set the readable flag on your connections:

```
my $conn = SOAP::Lite;

$conn->readable(1);
```

This will make the messages sent by the client more readable, but will not affect messages received from the server.

5.4 Debugging with C#

5.4.1 Fault Handlers

Pleae refer to section 2.2 for details on how to inspect any SOAP Faults that are raised as a result of a server or transport error.

5.4.2 Permissions Problems

The .NET environment enforces stringent security checks by default.

For example, by default, your Control API application cannot generate an HTTP request to a foreign site (such as the Zeus Admin Server) unless the application is running from a 'trusted location'. Remote filesystems which are locally mounted are untrusted, whereas local filesystems are trusted.

The location of your Control API application may affect whether it functions correctly or not.

5.5 Debugging with Java

5.5.1 Fault Handlers

Pleae refer to section 2.2 for details on how to inspect any SOAP Faults that are raised as a result of a server or transport error.

5.5.2 Tracing

For full SOAP tracing, you can run your Zeus Control API application as follows:

```
$ java -Djavax.net.debug=all listVS
```

Alternatively, you can enable debugging within your application:

```
System.setProperty( "javax.net.debug", "all" );
```

Function Reference

6.1 About the Zeus Control API functions

Zeus Control API functions generally operate on lists of configurations. For example, the VirtualServer `getEnabled()` function takes a list of virtual server names as its first argument, and returns a list of Boolean values, one for each named virtual server.

Some functions depend on compound structures for their arguments, and enumerated types are used to represent some configuration settings.

All of the methods, structures and enumerated types are specified in the WSDL interface files[8].

The `addRules()` and `getRules()` VirtualServer functions are good examples:

```
VirtualServer.Rule[][] getRules(
    String[] names
)

void addRules(
    String[] names
    VirtualServer.Rule[][] rules
)
```

Method prototypes for the VirtualServer getRules and addRules methods

---

[8] The WSDL interface specifications are located in `ZEUSHOME/zxtm/etc/wsdl/`

`getRules()` takes a list of virtual server names, returning a list of `VirtualServer.Rule` arrays:

```
struct VirtualServer.Rule {
    # The name of the rule.
    String name;

    # Whether the rule is enabled or not.
    Boolean enabled;

    # Whether the rule runs on every request response,
    # or just the first
    VirtualServer.RuleRunFlag run_frequency;
}
```

Definition of the VirtualServer.Rule structure

The VirtualServer.Rule structure includes an enumerated type:

```
enum VirtualServer.RuleRunFlag {
    # Run on every request or response
    run_every,

    # Run only on the first request or response
    only_first
}
```

Definition of the VirtualServer.RuleRunFlag enumerated type

Your SOAP toolkit will represent these WSDL methods, structures and enumerated types in a form appropriate for the language in use:

- Perl uses methods in the SOAP::Lite object. Structures map straightforwardly onto Perl associative arrays. You need to provide an explicit deserializer to typecast enumerated type values into string values. See chapter 3 for details.

- The C# and Java toolkits provide a means to convert the WSDL files into C# or Java source files, with fully typed classes, structures and enumerations to represent the SOAP methods, structures and enumerated types.

Take a look at section 4.3 for a worked example that illustrates the use of the methods, structures and enumerations.

6.2 VirtualServer

URI: `http://soap.zeus.com/zxtm/1.0/VirtualServer/`

The VirtualServer interface allows management of Virtual Server objects. Using this interface, you can create, delete and rename virtual server objects, and manage their configuration.

6.2.1 Methods

addCompressionMIMETypes(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

For each named virtual server, add new MIME types to the list of types to compress.

```
void addCompressionMIMETypes(
   String[] names
   String[][] values
)
```

addCompressionMIMETypesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

For each named virtual server, add new MIME types to the list of types to compress. This is a location specific function, any action will operate on the specified location.

```
void addCompressionMIMETypesByLocation(
   String location
   String[] names
   String[][] values
)
```

addResponseRules(names, rules) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new rules to be run on server responses for each of the named virtual servers. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in.

```
void addResponseRules(
   String[] names
   VirtualServer.Rule[][] rules
)
```

addResponseRulesByLocation(location, names, rules) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new rules to be run on server responses for each of the named virtual servers. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in. This is a location specific function, any action will operate on the specified location.

```
void addResponseRulesByLocation(
   String location
   String[] names
   VirtualServer.Rule[][] rules
)
```

addRules(names, rules) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new rules to be run on client requests for each of the named virtual servers. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in.

```
void addRules(
   String[] names
   VirtualServer.Rule[][] rules
)
```

addRulesByLocation(location, names, rules) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new rules to be run on client requests for each of the named virtual servers. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in. This is a location specific function, any action will operate on the specified location.

```
void addRulesByLocation(
   String location
   String[] names
   VirtualServer.Rule[][] rules
)
```

addSSLClientCertificateAuthorities(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new certificate authorities for validating client certificates for each of the named virtual servers.

```
void addSSLClientCertificateAuthorities(
   String[] names
   String[][] values
```

```
)
```

addSSLClientCertificateAuthoritiesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new certificate authorities for validating client certificates for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void addSSLClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

addSSLNeverExpiringClientCertificateAuthorities(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed, for each of the named virtual servers.

```
void addSSLNeverExpiringClientCertificateAuthorities(
   String[] names
   String[][] values
)
```

addSSLNeverExpiringClientCertificateAuthoritiesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void addSSLNeverExpiringClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

addSSLSites(names, ssl_sites) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Adds the specified SSLSite objects to the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog.

```
void addSSLSites(
   String[] names
```

```
     VirtualServer.SSLSite[][] ssl_sites
  )
```

addSSLSitesByLocation(location, names, ssl_sites) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Adds the specified SSLSite objects to the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog. This is a location specific function, any action will operate on the specified location.

```
  void addSSLSitesByLocation(
     String location
     String[] names
     VirtualServer.SSLSite[][] ssl_sites
  )
```

addVirtualServer(names, info) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidInput

Add each virtual servers, using the provided BasicInfo.

```
  void addVirtualServer(
     String[] names
     VirtualServer.BasicInfo[] info
  )
```

copyVirtualServer(names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError

Rename each of the named virtual servers.

```
  void copyVirtualServer(
     String[] names
     String[] new_names
  )
```

deleteSSLSites(names, site_ips) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Deletes the SSLSite objects that act on the IP addresses in the site_ips array for each of the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog.

```
  void deleteSSLSites(
     String[] names
     String[][] site_ips
```

```
)
```

deleteSSLSitesByLocation(location, names, site_ips) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Deletes the SSLSite objects that act on the IP addresses in the site_ips array for each of the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog. This is a location specific function, any action will operate on the specified location.

```
void deleteSSLSitesByLocation(
    String location
    String[] names
    String[][] site_ips
)
```

deleteVirtualServer(names) throws ObjectDoesNotExist, DeploymentError

Delete each of the named virtual servers.

```
void deleteVirtualServer(
    String[] names
)
```

editSSLSites(names, site_ips, ssl_sites) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Edits the SSLSite objects that act on the IP addresses in the site_ips array for each of the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog.

```
void editSSLSites(
    String[] names
    String[][] site_ips
    VirtualServer.SSLSite[][] ssl_sites
)
```

editSSLSitesByLocation(location, names, site_ips, ssl_sites) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Edits the SSLSite objects that act on the IP addresses in the site_ips array for each of the named virtual servers. These objects are mappings between destination addresses and the certificate used for SSL decryption those addresses. Each certificate is the name of an item in the SSL Certificates Catalog. This is a location specific function, any action will operate on the specified location.

```
void editSSLSitesByLocation(
   String location
   String[] names
   String[][] site_ips
   VirtualServer.SSLSite[][] ssl_sites
)
```

getAddClusterClientIPHeader(names) throws ObjectDoesNotExist

Get whether a 'X-Cluster-Client-Ip' header should be added to each HTTP request, for each of the named virtual servers. The 'X-Cluster-Client-Ip' header contains the client's IP address.

```
Boolean[] getAddClusterClientIPHeader(
   String[] names
)
```

getAddClusterClientIPHeaderByLocation(location, names) throws ObjectDoesNotExist

Get whether a 'X-Cluster-Client-Ip' header should be added to each HTTP request, for each of the named virtual servers. The 'X-Cluster-Client-Ip' header contains the client's IP address. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getAddClusterClientIPHeaderByLocation(
   String location
   String[] names
)
```

getBandwidthClass(names) throws ObjectDoesNotExist

Get the Bandwidth Class that each of the named virtual servers uses.

```
String[] getBandwidthClass(
   String[] names
)
```

getBandwidthClassByLocation(location, names) throws ObjectDoesNotExist

Get the Bandwidth Class that each of the named virtual servers uses. This is a location specific function, any action will operate on the specified location.

```
String[] getBandwidthClassByLocation(
   String location
   String[] names
)
```

getBasicInfo(names) throws ObjectDoesNotExist

Get the basic information for each of the named virtual servers. This information includes the port, the protocol the virtual server handles and the default pool for the traffic.

```
VirtualServer.BasicInfo[] getBasicInfo(
   String[] names
)
```

getBasicInfoByLocation(location, names) throws ObjectDoesNotExist

Get the basic information for each of the named virtual servers. This information includes the port, the protocol the virtual server handles and the default pool for the traffic. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.BasicInfo[] getBasicInfoByLocation(
   String location
   String[] names
)
```

getCompressUnknownSize(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should compress documents with no given size.

```
Boolean[] getCompressUnknownSize(
   String[] names
)
```

getCompressUnknownSizeByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should compress documents with no given size. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getCompressUnknownSizeByLocation(
   String location
   String[] names
)
```

getCompressionEnabled(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should compress web pages before sending to the client.

```
Boolean[] getCompressionEnabled(
   String[] names
)
```

getCompressionEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should compress web pages before sending to the client. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getCompressionEnabledByLocation(
   String location
   String[] names
)
```

getCompressionLevel(names) throws ObjectDoesNotExist

Get the gzip compression level, for each of the named virtual servers.

```
Unsigned Integer[] getCompressionLevel(
   String[] names
)
```

getCompressionLevelByLocation(location, names) throws ObjectDoesNotExist

Get the gzip compression level, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getCompressionLevelByLocation(
   String location
   String[] names
)
```

getCompressionMIMETypes(names) throws ObjectDoesNotExist

Get the list of MIME types to compress, for each of the named virtual servers.

```
String[][] getCompressionMIMETypes(
   String[] names
)
```

getCompressionMIMETypesByLocation(location, names) throws ObjectDoesNotExist

Get the list of MIME types to compress, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[][] getCompressionMIMETypesByLocation(
   String location
   String[] names
)
```

getCompressionMaxSize(names) throws ObjectDoesNotExist

Get the maximum document size to compress, in bytes, for each of the named virtual servers. A document size of '0' means 'unlimited'.

```
Unsigned Integer[] getCompressionMaxSize(
   String[] names
)
```

getCompressionMaxSizeByLocation(location, names) throws ObjectDoesNotExist

Get the maximum document size to compress, in bytes, for each of the named virtual servers. A document size of '0' means 'unlimited'. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getCompressionMaxSizeByLocation(
   String location
   String[] names
)
```

getCompressionMinSize(names) throws ObjectDoesNotExist

Get the minimum document size to compress, in bytes, for each of the named virtual servers.

```
Unsigned Integer[] getCompressionMinSize(
   String[] names
)
```

getCompressionMinSizeByLocation(location, names) throws ObjectDoesNotExist

Get the minimum document size to compress, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getCompressionMinSizeByLocation(
   String location
   String[] names
)
```

getConnectTimeout(names) throws ObjectDoesNotExist

Get the time to wait for data from a new connection, in seconds, for each of the named virtual servers. If no data is received in this time, the connection will be closed.

```
Unsigned Integer[] getConnectTimeout(
   String[] names
```

```
)
```

getConnectTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time to wait for data from a new connection, in seconds, for each of the named virtual servers. If no data is received in this time, the connection will be closed. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getConnectTimeoutByLocation(
   String location
   String[] names
)
```

getCookieDomainRewriteMode(names) throws ObjectDoesNotExist

Get how each of the named virtual servers should rewrite the domain portion of cookies set by a back-end web server.

```
VirtualServer.CookieDomainRewriteMode[] getCookieDomainRewriteMode(
   String[] names
)
```

getCookieDomainRewriteModeByLocation(location, names) throws ObjectDoesNotExist

Get how each of the named virtual servers should rewrite the domain portion of cookies set by a back-end web server. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.CookieDomainRewriteMode[]
getCookieDomainRewriteModeByLocation(
   String location
   String[] names
)
```

getCookieNamedDomain(names) throws ObjectDoesNotExist

Get the domain to use when rewriting cookie domains, for each of the named virtual servers.

```
String[] getCookieNamedDomain(
   String[] names
)
```

getCookieNamedDomainByLocation(location, names) throws ObjectDoesNotExist

Get the domain to use when rewriting cookie domains, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[] getCookieNamedDomainByLocation(
   String location
   String[] names
)
```

getCookiePathRewrite(names) throws ObjectDoesNotExist

For each of the named virtual servers, get the regex and replacement for rewriting the path portion of a cookie.

```
VirtualServer.RegexReplacement[] getCookiePathRewrite(
   String[] names
)
```

getCookiePathRewriteByLocation(location, names) throws ObjectDoesNotExist

For each of the named virtual servers, get the regex and replacement for rewriting the path portion of a cookie. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.RegexReplacement[] getCookiePathRewriteByLocation(
   String location
   String[] names
)
```

getCookieSecureFlagRewriteMode(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should modify the 'secure' tag of cookies set by a back-end web server.

```
VirtualServer.CookieSecureFlagRewriteMode[]
getCookieSecureFlagRewriteMode(
   String[] names
)
```

getCookieSecureFlagRewriteModeByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should modify the 'secure' tag of cookies set by a back-end web server. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.CookieSecureFlagRewriteMode[]
getCookieSecureFlagRewriteModeByLocation(
   String location
   String[] names
)
```

getDefaultPool(names) throws ObjectDoesNotExist

Get the default Pool that traffic is sent to for each of the named virtual servers.

```
String[] getDefaultPool(
   String[] names
)
```

getDefaultPoolByLocation(location, names) throws ObjectDoesNotExist

Get the default Pool that traffic is sent to for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[] getDefaultPoolByLocation(
   String location
   String[] names
)
```

getEnabled(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers is enabled (i.e. serving traffic).

```
Boolean[] getEnabled(
   String[] names
)
```

getEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers is enabled (i.e. serving traffic). This is a location specific function, any action will operate on the specified location.

```
Boolean[] getEnabledByLocation(
   String location
   String[] names
)
```

getErrorFile(names) throws ObjectDoesNotExist

Get the file names of the error texts that each of the named virtual servers will send back to a client in case of back-end or internal errors.

```
String[] getErrorFile(
   String[] names
)
```

getErrorFileByLocation(location, names) throws ObjectDoesNotExist

Get the file names of the error texts that each of the named virtual servers will send back to a client in case of back-end or internal errors. This is a location specific function, any action will operate on the specified location.

```
String[] getErrorFileByLocation(
   String location
   String[] names
)
```

getFTPDataSourcePort(names) throws ObjectDoesNotExist

Get the source port each of the named virtual servers should use for active-mode FTP data connections. If 0, a random high port will be used, otherwise the specified port will be used. If a port below 1024 is required you must first explicitly permit use of low ports with the ftp_data_bind_low global setting.

```
Unsigned Integer[] getFTPDataSourcePort(
   String[] names
)
```

getFTPDataSourcePortByLocation(location, names) throws ObjectDoesNotExist

Get the source port each of the named virtual servers should use for active-mode FTP data connections. If 0, a random high port will be used, otherwise the specified port will be used. If a port below 1024 is required you must first explicitly permit use of low ports with the ftp_data_bind_low global setting. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getFTPDataSourcePortByLocation(
   String location
   String[] names
)
```

getFTPForceClientSecure(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should require incoming FTP data connections (from clients) to originate from the same IP address as the corresponding control connection.

```
Boolean[] getFTPForceClientSecure(
   String[] names
)
```

getFTPForceClientSecureByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should require incoming FTP data connections (from clients) to originate from the same IP address as the corresponding control connection. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getFTPForceClientSecureByLocation(
   String location
   String[] names
)
```

getFTPForceServerSecure(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should require incoming FTP data connections (from nodes) to originate from the same IP address as the corresponding control connection.

```
Boolean[] getFTPForceServerSecure(
   String[] names
)
```

getFTPForceServerSecureByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should require incoming FTP data connections (from nodes) to originate from the same IP address as the corresponding control connection. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getFTPForceServerSecureByLocation(
   String location
   String[] names
)
```

getFTPPortRange(names) throws ObjectDoesNotExist

Get the port range used for FTP data connections for each of the named virtual servers.

```
VirtualServer.FTPPortRange[] getFTPPortRange(
   String[] names
)
```

getFTPPortRangeByLocation(location, names) throws ObjectDoesNotExist

Get the port range used for FTP data connections for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.FTPPortRange[] getFTPPortRangeByLocation(
   String location
   String[] names
)
```

getFTPSSLData(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should use SSL on the data connection as well as the control connection

```
Boolean[] getFTPSSLData(
   String[] names
)
```

getFTPSSLDataByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should use SSL on the data connection as well as the control connection This is a location specific function, any action will operate on the specified location.

```
Boolean[] getFTPSSLDataByLocation(
   String location
   String[] names
)
```

getKeepalive(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should allow clients to maintain keepalive connections.

```
Boolean[] getKeepalive(
   String[] names
)
```

getKeepaliveByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should allow clients to maintain keepalive connections. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getKeepaliveByLocation(
   String location
   String[] names
)
```

getKeepaliveTimeout(names) throws ObjectDoesNotExist

Get the time that an idle keepalive connection should be kept open for, in seconds, for each of the named virtual servers.

```
Unsigned Integer[] getKeepaliveTimeout(
   String[] names
)
```

getKeepaliveTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time that an idle keepalive connection should be kept open for, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getKeepaliveTimeoutByLocation(
   String location
   String[] names
)
```

getListenAddresses(names) throws ObjectDoesNotExist

Get the specific IP addresses and hostnames that each of the named virtual servers are listening on. This will return an empty array for a virtual server if it is listening on all addresses.

```
String[][] getListenAddresses(
   String[] names
)
```

getListenAddressesByLocation(location, names) throws ObjectDoesNotExist

Get the specific IP addresses and hostnames that each of the named virtual servers are listening on. This will return an empty array for a virtual server if it is listening on all addresses. This is a location specific function, any action will operate on the specified location.

```
String[][] getListenAddressesByLocation(
```

```
    String location
    String[] names
)
```

getListenOnAllAddresses(names) throws ObjectDoesNotExist

For each of the named virtual servers, gets whether the virtual server is listening on all IP addresses

```
Boolean[] getListenOnAllAddresses(
    String[] names
)
```

getListenOnAllAddressesByLocation(location, names) throws ObjectDoesNotExist

For each of the named virtual servers, gets whether the virtual server is listening on all IP addresses This is a location specific function, any action will operate on the specified location.

```
Boolean[] getListenOnAllAddressesByLocation(
    String location
    String[] names
)
```

getListenTrafficIPGroups(names) throws ObjectDoesNotExist

Get the specific Traffic IP Groups that each named virtual server listens on. This will return an empty array for a virtual server if it is listening on all addresses.

```
String[][] getListenTrafficIPGroups(
    String[] names
)
```

getListenTrafficIPGroupsByLocation(location, names) throws ObjectDoesNotExist

Get the specific Traffic IP Groups that each named virtual server listens on. This will return an empty array for a virtual server if it is listening on all addresses. This is a location specific function, any action will operate on the specified location.

```
String[][] getListenTrafficIPGroupsByLocation(
    String location
    String[] names
)
```

getLocationDefaultRewriteMode(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should rewrite the 'Location' header. The rewrite is only performed if the location rewrite regex didn't match.

```
VirtualServer.LocationDefaultRewriteMode[]
getLocationDefaultRewriteMode(
    String[] names
)
```

getLocationDefaultRewriteModeByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should rewrite the 'Location' header. The rewrite is only performed if the location rewrite regex didn't match. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.LocationDefaultRewriteMode[]
getLocationDefaultRewriteModeByLocation(
    String location
    String[] names
)
```

getLocationRewrite(names) throws ObjectDoesNotExist

For each of the named virtual servers, get the regex, and replacement for rewriting any 'Location' headers.

```
VirtualServer.RegexReplacement[] getLocationRewrite(
    String[] names
)
```

getLocationRewriteByLocation(location, names) throws ObjectDoesNotExist

For each of the named virtual servers, get the regex, and replacement for rewriting any 'Location' headers. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.RegexReplacement[] getLocationRewriteByLocation(
    String location
    String[] names
)
```

getLogClientConnectionFailures(names) throws ObjectDoesNotExist

Get whether the virtual server will log client connection failures.

```
Boolean[] getLogClientConnectionFailures(
    String[] names
```

```
)
```

getLogClientConnectionFailuresByLocation(location, names) throws ObjectDoesNotExist

Get whether the virtual server will log client connection failures. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getLogClientConnectionFailuresByLocation(
   String location
   String[] names
)
```

getLogEnabled(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should log each connection to a disk on the file system.

```
Boolean[] getLogEnabled(
   String[] names
)
```

getLogEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should log each connection to a disk on the file system. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getLogEnabledByLocation(
   String location
   String[] names
)
```

getLogFilename(names) throws ObjectDoesNotExist

Get the name of the file used to store request logs, for each of the named virtual servers.

```
String[] getLogFilename(
   String[] names
)
```

getLogFilenameByLocation(location, names) throws ObjectDoesNotExist

Get the name of the file used to store request logs, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[] getLogFilenameByLocation(
   String location
```

```
        String[] names
    )
```

getLogFormat(names) throws ObjectDoesNotExist

Get the log file format for each of the named virtual servers.

```
    String[] getLogFormat(
        String[] names
    )
```

getLogFormatByLocation(location, names) throws ObjectDoesNotExist

Get the log file format for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
    String[] getLogFormatByLocation(
        String location
        String[] names
    )
```

getLogSSLFailures(names) throws ObjectDoesNotExist

Get whether the virtual server will log ssl failures.

```
    Boolean[] getLogSSLFailures(
        String[] names
    )
```

getLogSSLFailuresByLocation(location, names) throws ObjectDoesNotExist

Get whether the virtual server will log ssl failures. This is a location specific function, any action will operate on the specified location.

```
    Boolean[] getLogSSLFailuresByLocation(
        String location
        String[] names
    )
```

getLogServerConnectionFailures(names) throws ObjectDoesNotExist

Get whether the virtual server will log server connection failures.

```
    Boolean[] getLogServerConnectionFailures(
        String[] names
    )
```

getLogServerConnectionFailuresByLocation(location, names) throws ObjectDoesNotExist

Get whether the virtual server will log server connection failures. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getLogServerConnectionFailuresByLocation(
   String location
   String[] names
)
```

getMIMEAutoDetect(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should auto-detect MIME types if the server does not provide them.

```
Boolean[] getMIMEAutoDetect(
   String[] names
)
```

getMIMEAutoDetectByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should auto-detect MIME types if the server does not provide them. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getMIMEAutoDetectByLocation(
   String location
   String[] names
)
```

getMIMEDefaultType(names) throws ObjectDoesNotExist

Get the MIME type that the server uses as its 'default', for each of the named virtual servers. Responses with this mime type will be auto-corrected by the virtual server if this setting is enabled.

```
String[] getMIMEDefaultType(
   String[] names
)
```

getMIMEDefaultTypeByLocation(location, names) throws ObjectDoesNotExist

Get the MIME type that the server uses as its 'default', for each of the named virtual servers. Responses with this mime type will be auto-corrected by the virtual server if this setting is enabled. This is a location specific function, any action will operate on the specified location.

```
String[] getMIMEDefaultTypeByLocation(
```

```
    String location
    String[] names
)
```

getMaxClientBuffer(names) throws ObjectDoesNotExist

Get the amount of memory used to store data sent by the client, in bytes, for each of the named virtual servers.

```
Unsigned Integer[] getMaxClientBuffer(
    String[] names
)
```

getMaxClientBufferByLocation(location, names) throws ObjectDoesNotExist

Get the amount of memory used to store data sent by the client, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxClientBufferByLocation(
    String location
    String[] names
)
```

getMaxServerBuffer(names) throws ObjectDoesNotExist

Get the amount of memory used to store data returned by the server, in bytes, for each of the named virtual servers.

```
Unsigned Integer[] getMaxServerBuffer(
    String[] names
)
```

getMaxServerBufferByLocation(location, names) throws ObjectDoesNotExist

Get the amount of memory used to store data returned by the server, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxServerBufferByLocation(
    String location
    String[] names
)
```

getNote(names) throws ObjectDoesNotExist

Get the note for each of the named virtual servers.

```
String[] getNote(
```

```
    String[] names
)
```

getPort(names) throws ObjectDoesNotExist

Get the port that each of the named virtual servers listens on for incoming connections.

```
Unsigned Integer[] getPort(
    String[] names
)
```

getPortByLocation(location, names) throws ObjectDoesNotExist

Get the port that each of the named virtual servers listens on for incoming connections. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getPortByLocation(
    String location
    String[] names
)
```

getProtection(names) throws ObjectDoesNotExist

Get the Service Protection Settings that are used to protect each of the named virtual servers.

```
String[] getProtection(
    String[] names
)
```

getProtectionByLocation(location, names) throws ObjectDoesNotExist

Get the Service Protection Settings that are used to protect each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[] getProtectionByLocation(
    String location
    String[] names
)
```

getProtocol(names) throws ObjectDoesNotExist

Get the protocol that each of the named virtual servers uses.

```
VirtualServer.Protocol[] getProtocol(
    String[] names
)
```

getProxyClose(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should send a FIN packet on to the back-end server when it is received from the client. The alternative is to close the connection to the client immediately. If the traffic manager is responding to the request itself, enabling this setting will cause the traffic manager to continue writing the response even after it has received a FIN from the client.

```
Boolean[] getProxyClose(
   String[] names
)
```

getProxyCloseByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should send a FIN packet on to the back-end server when it is received from the client. The alternative is to close the connection to the client immediately. If the traffic manager is responding to the request itself, enabling this setting will cause the traffic manager to continue writing the response even after it has received a FIN from the client. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getProxyCloseByLocation(
   String location
   String[] names
)
```

getRTSPPortRange(names) throws ObjectDoesNotExist

Get the port range used for RTSP streaming data connections, for each of the named virtual servers.

```
VirtualServer.PortRange[] getRTSPPortRange(
   String[] names
)
```

getRTSPPortRangeByLocation(location, names) throws ObjectDoesNotExist

Get the port range used for RTSP streaming data connections, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.PortRange[] getRTSPPortRangeByLocation(
   String location
   String[] names
)
```

getRequestSyslogEnabled(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should log each connection to a remote syslog server.

```
Boolean[] getRequestSyslogEnabled(
   String[] names
)
```

getRequestSyslogEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should log each connection to a remote syslog server. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getRequestSyslogEnabledByLocation(
   String location
   String[] names
)
```

getRequestSyslogFormat(names) throws ObjectDoesNotExist

Get the remote log line format for each of the named virtual servers.

```
String[] getRequestSyslogFormat(
   String[] names
)
```

getRequestSyslogFormatByLocation(location, names) throws ObjectDoesNotExist

Get the remote log line format for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[] getRequestSyslogFormatByLocation(
   String location
   String[] names
)
```

getRequestSyslogIPEndpoint(names) throws ObjectDoesNotExist

Get the remote syslog endpoint for each of the named virtual servers

```
String[] getRequestSyslogIPEndpoint(
   String[] names
)
```

getRequestSyslogIPEndpointByLocation(location, names) throws ObjectDoesNotExist

Get the remote syslog endpoint for each of the named virtual servers This is a location specific function, any action will operate on the specified location.

```
String[] getRequestSyslogIPEndpointByLocation(
   String location
   String[] names
)
```

getRequestTracingEnabled(names) throws ObjectDoesNotExist

Get whether to record a detailed list of processing history for each request.

```
Boolean[] getRequestTracingEnabled(
   String[] names
)
```

getRequestTracingEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether to record a detailed list of processing history for each request. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getRequestTracingEnabledByLocation(
   String location
   String[] names
)
```

getRequestTracingIO(names) throws ObjectDoesNotExist

Get whether to record a detailed list of every IO event in the processing history for each request.

```
Boolean[] getRequestTracingIO(
   String[] names
)
```

getRequestTracingIOByLocation(location, names) throws ObjectDoesNotExist

Get whether to record a detailed list of every IO event in the processing history for each request. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getRequestTracingIOByLocation(
   String location
   String[] names
)
```

getResponseRules(names) throws ObjectDoesNotExist

Get the rules that are run on server responses for each of the named virtual servers.

```
VirtualServer.Rule[][] getResponseRules(
   String[] names
)
```

getResponseRulesByLocation(location, names) throws ObjectDoesNotExist

Get the rules that are run on server responses for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.Rule[][] getResponseRulesByLocation(
   String location
   String[] names
)
```

getRewriteSIPURI(names) throws ObjectDoesNotExist

Get whether the Request-URI of SIP requests will be replaced with the selected back-end node's address.

```
Boolean[] getRewriteSIPURI(
   String[] names
)
```

getRewriteSIPURIByLocation(location, names) throws ObjectDoesNotExist

Get whether the Request-URI of SIP requests will be replaced with the selected back-end node's address. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getRewriteSIPURIByLocation(
   String location
   String[] names
)
```

getRules(names) throws ObjectDoesNotExist

Get the rules that are run on client requests for each of the named virtual servers.

```
VirtualServer.Rule[][] getRules(
   String[] names
)
```

getRulesByLocation(location, names) throws ObjectDoesNotExist

Get the rules that are run on client requests for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.Rule[][] getRulesByLocation(
   String location
   String[] names
)
```

getSIPDangerousRequestMode(names) throws ObjectDoesNotExist

Get what should be done with requests that contain body data and should be routed to an external IP.

```
VirtualServer.SIPDangerousRequestMode[] getSIPDangerousRequestMode(
   String[] names
)
```

getSIPDangerousRequestModeByLocation(location, names) throws ObjectDoesNotExist

Get what should be done with requests that contain body data and should be routed to an external IP. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.SIPDangerousRequestMode[]
getSIPDangerousRequestModeByLocation(
   String location
   String[] names
)
```

getSIPFollowRoute(names) throws ObjectDoesNotExist

Get whether to follow routing information in SIP requests.

```
Boolean[] getSIPFollowRoute(
   String[] names
)
```

getSIPFollowRouteByLocation(location, names) throws ObjectDoesNotExist

Get whether to follow routing information in SIP requests. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSIPFollowRouteByLocation(
   String location
   String[] names
)
```

getSIPMaxConnectionMemory(names) throws ObjectDoesNotExist

Get maximum memory per connection.

```
Unsigned Integer[] getSIPMaxConnectionMemory(
    String[] names
)
```

getSIPMaxConnectionMemoryByLocation(location, names) throws ObjectDoesNotExist

Get maximum memory per connection. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getSIPMaxConnectionMemoryByLocation(
    String location
    String[] names
)
```

getSIPMode(names) throws ObjectDoesNotExist

Get which mode of operation the SIP virtual server should run in.

```
VirtualServer.SIPMode[] getSIPMode(
    String[] names
)
```

getSIPModeByLocation(location, names) throws ObjectDoesNotExist

Get which mode of operation the SIP virtual server should run in. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.SIPMode[] getSIPModeByLocation(
    String location
    String[] names
)
```

getSIPPortRange(names) throws ObjectDoesNotExist

Get the port range used for SIP data connections, for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode.

```
VirtualServer.PortRange[] getSIPPortRange(
    String[] names
)
```

getSIPPortRangeByLocation(location, names) throws ObjectDoesNotExist

Get the port range used for SIP data connections, for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.PortRange[] getSIPPortRangeByLocation(
   String location
   String[] names
)
```

getSIPStreamingTimeout(names) throws ObjectDoesNotExist

Get the time, in seconds, after which a UDP stream will timeout if it has not seen any data.

```
Unsigned Integer[] getSIPStreamingTimeout(
   String[] names
)
```

getSIPStreamingTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time, in seconds, after which a UDP stream will timeout if it has not seen any data. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getSIPStreamingTimeoutByLocation(
   String location
   String[] names
)
```

getSSLCertificate(names) throws ObjectDoesNotExist

Get the name of the default SSL Certificate that is used for SSL decryption for each of the named virtual servers. This is the name of an item in the SSL Certificates Catalog.

```
String[] getSSLCertificate(
   String[] names
)
```

getSSLCertificateByLocation(location, names) throws ObjectDoesNotExist

Get the name of the default SSL Certificate that is used for SSL decryption for each of the named virtual servers. This is the name of an item in the SSL Certificates Catalog. This is a location specific function, any action will operate on the specified location.

```
String[] getSSLCertificateByLocation(
   String location
   String[] names
)
```

getSSLClientCertificateAuthorities(names) throws ObjectDoesNotExist

Get the certificate authorities that are trusted for validating client certificates, for each of the named virtual servers.

```
String[][] getSSLClientCertificateAuthorities(
   String[] names
)
```

getSSLClientCertificateAuthoritiesByLocation(location, names) throws ObjectDoesNotExist

Get the certificate authorities that are trusted for validating client certificates, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
String[][] getSSLClientCertificateAuthoritiesByLocation(
   String location
   String[] names
)
```

getSSLClientCertificateHeaders(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should add HTTP headers to each request to show the data in the client certificate.

```
VirtualServer.SSLClientCertificateHeaders[]
getSSLClientCertificateHeaders(
   String[] names
)
```

getSSLClientCertificateHeadersByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should add HTTP headers to each request to show the data in the client certificate. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.SSLClientCertificateHeaders[]
getSSLClientCertificateHeadersByLocation(
   String location
   String[] names
)
```

getSSLDecrypt(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should decrypt SSL traffic.

```
Boolean[] getSSLDecrypt(
   String[] names
)
```

getSSLDecryptByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should decrypt SSL traffic. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLDecryptByLocation(
   String location
   String[] names
)
```

getSSLExpectStartTLS(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should upgrade SMTP connections to SSL using the STARTTLS command.

```
Boolean[] getSSLExpectStartTLS(
   String[] names
)
```

getSSLExpectStartTLSByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should upgrade SMTP connections to SSL using the STARTTLS command. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLExpectStartTLSByLocation(
   String location
   String[] names
)
```

getSSLHeaders(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should add HTTP headers to each request to show SSL connection parameters.

```
Boolean[] getSSLHeaders(
   String[] names
)
```

getSSLHeadersByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should add HTTP headers to each request to show SSL connection parameters. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLHeadersByLocation(
    String location
    String[] names
)
```

getSSLLogEnabled(names) throws ObjectDoesNotExist

This method is now obsolete. SSL logging is now done if LogConnectionFailures is enabled. Use VirtualServer.getLogConnectionFailures and VirtualServer.getLogConnection failures to control this configuration.

```
Boolean[] getSSLLogEnabled(
    String[] names
)
```

getSSLNeverExpiringClientCertificateAuthorities(names) throws ObjectDoesNotExist

Get the CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed.

```
String[][] getSSLNeverExpiringClientCertificateAuthorities(
    String[] names
)
```

getSSLNeverExpiringClientCertificateAuthoritiesByLocation(location, names) throws ObjectDoesNotExist

Get the CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed. This is a location specific function, any action will operate on the specified location.

```
String[][] getSSLNeverExpiringClientCertificateAuthoritiesByLocation(
    String location
    String[] names
)
```

getSSLRequestClientCertMode(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should request (or require) an identifying certificate from each client.

```
VirtualServer.SSLRequestClientCertMode[] getSSLRequestClientCertMode(
```

```
    String[] names
)
```

getSSLRequestClientCertModeByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should request (or require) an identifying certificate from each client. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.SSLRequestClientCertMode[]
getSSLRequestClientCertModeByLocation(
    String location
    String[] names
)
```

getSSLSendCloseAlerts(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should send a close alert when initiating SSL socket disconnections.

```
Boolean[] getSSLSendCloseAlerts(
    String[] names
)
```

getSSLSendCloseAlertsByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should send a close alert when initiating SSL socket disconnections. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLSendCloseAlertsByLocation(
    String location
    String[] names
)
```

getSSLSites(names) throws ObjectDoesNotExist

Gets a list of mappings between destination addresses and the certificate used for SSL decryption those addresses, for each of the named virtual servers. Each certificate is the name of an item in the SSL Certificates Catalog.

```
VirtualServer.SSLSite[][] getSSLSites(
    String[] names
)
```

getSSLSitesByLocation(location, names) throws ObjectDoesNotExist

Gets a list of mappings between destination addresses and the certificate used for SSL decryption those addresses, for each of the named virtual servers. Each certificate is the name of an item in the SSL Certificates Catalog. This is a location specific function, any action will operate on the specified location.

```
VirtualServer.SSLSite[][] getSSLSitesByLocation(
   String location
   String[] names
)
```

getSSLTrustMagic(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should decode extra information on the true origin of an SSL connection. This information is prefixed onto an incoming SSL connection from another traffic manager.

```
Boolean[] getSSLTrustMagic(
   String[] names
)
```

getSSLTrustMagicByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should decode extra information on the true origin of an SSL connection. This information is prefixed onto an incoming SSL connection from another traffic manager. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLTrustMagicByLocation(
   String location
   String[] names
)
```

getServerfirstBanner(names) throws ObjectDoesNotExist

Get the banner that each of the named virtual servers sends to clients for server-first protocols such as POP, SMTP and IMAP.

```
String[] getServerfirstBanner(
   String[] names
)
```

getServerfirstBannerByLocation(location, names) throws ObjectDoesNotExist

Get the banner that each of the named virtual servers sends to clients for server-first protocols such as POP, SMTP and IMAP. This is a location specific function, any action will operate on the specified location.

```
String[] getServerfirstBannerByLocation(
   String location
   String[] names
)
```

getServiceLevelMonitoring(names) throws ObjectDoesNotExist

Get the Service Level Monitoring class that each of the named virtual servers uses.

```
String[] getServiceLevelMonitoring(
   String[] names
)
```

getServiceLevelMonitoringByLocation(location, names) throws ObjectDoesNotExist

Get the Service Level Monitoring class that each of the named virtual servers uses. This is a location specific function, any action will operate on the specified location.

```
String[] getServiceLevelMonitoringByLocation(
   String location
   String[] names
)
```

getSipTransactionTimeout(names) throws ObjectDoesNotExist

Get the time after which an incomplete transaction should be discarded, in seconds, for each of the named virtual servers.

```
Unsigned Integer[] getSipTransactionTimeout(
   String[] names
)
```

getSipTransactionTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time after which an incomplete transaction should be discarded, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getSipTransactionTimeoutByLocation(
   String location
   String[] names
)
```

getTimeout(names) throws ObjectDoesNotExist

Get the time to wait for data on an already established connection, in seconds, for each of the named virtual servers.

```
Unsigned Integer[] getTimeout(
   String[] names
)
```

getTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time to wait for data on an already established connection, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getTimeoutByLocation(
   String location
   String[] names
)
```

getUDPResponseDatagramsExpected(names) throws ObjectDoesNotExist

Get the expected number of UDP datagrams in the response, for each of the named virtual servers. For simple request/response protocols a value of '1' should be used. If set to -1, the connection will not be discarded until the udp_timeout is reached.

```
Integer[] getUDPResponseDatagramsExpected(
   String[] names
)
```

getUDPResponseDatagramsExpectedByLocation(location, names) throws ObjectDoesNotExist

Get the expected number of UDP datagrams in the response, for each of the named virtual servers. For simple request/response protocols a value of '1' should be used. If set to -1, the connection will not be discarded until the udp_timeout is reached. This is a location specific function, any action will operate on the specified location.

```
Integer[] getUDPResponseDatagramsExpectedByLocation(
   String location
   String[] names
)
```

getUDPTimeout(names) throws ObjectDoesNotExist

Get the time after which an idle UDP connection should be discarded and resources reclaimed, in seconds, for each of the named virtual servers.

```
Unsigned Integer[] getUDPTimeout(
```

```
     String[] names
   )
```

getUDPTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get the time after which an idle UDP connection should be discarded and resources reclaimed, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getUDPTimeoutByLocation(
   String location
   String[] names
)
```

getUseNagle(names) throws ObjectDoesNotExist

Get whether Nagle's algorithm should be used for TCP connections.

```
Boolean[] getUseNagle(
   String[] names
)
```

getUseNagleByLocation(location, names) throws ObjectDoesNotExist

Get whether Nagle's algorithm should be used for TCP connections. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getUseNagleByLocation(
   String location
   String[] names
)
```

getVirtualServerNames()

Gets the names of all the configured virtual servers.

```
String[] getVirtualServerNames()
```

getWebcacheControlOut(names) throws ObjectDoesNotExist

Get the Cache-Control header that should be sent with cached HTTP responses.

```
String[] getWebcacheControlOut(
   String[] names
)
```

getWebcacheControlOutByLocation(location, names) throws ObjectDoesNotExist

Get the Cache-Control header that should be sent with cached HTTP responses. This is a location specific function, any action will operate on the specified location.

```
String[] getWebcacheControlOutByLocation(
   String location
   String[] names
)
```

getWebcacheEnabled(names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should attempt to cache web server responses.

```
Boolean[] getWebcacheEnabled(
   String[] names
)
```

getWebcacheEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named virtual servers should attempt to cache web server responses. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getWebcacheEnabledByLocation(
   String location
   String[] names
)
```

getWebcacheErrorpageTime(names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should cache error pages for.

```
Unsigned Integer[] getWebcacheErrorpageTime(
   String[] names
)
```

getWebcacheErrorpageTimeByLocation(location, names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should cache error pages for. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getWebcacheErrorpageTimeByLocation(
   String location
   String[] names
)
```

getWebcacheRefreshTime(names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should consider re-fetching cached pages in.

```
Unsigned Integer[] getWebcacheRefreshTime(
   String[] names
)
```

getWebcacheRefreshTimeByLocation(location, names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should consider re-fetching cached pages in. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getWebcacheRefreshTimeByLocation(
   String location
   String[] names
)
```

getWebcacheTime(names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should cache web pages for.

```
Unsigned Integer[] getWebcacheTime(
   String[] names
)
```

getWebcacheTimeByLocation(location, names) throws ObjectDoesNotExist

Get the time periods that each of the named virtual servers should cache web pages for. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getWebcacheTimeByLocation(
   String location
   String[] names
)
```

removeCompressionMIMETypes(names, values) throws ObjectDoesNotExist, DeploymentError

For each named virtual server, remove new MIME types from the list of types to compress.

```
void removeCompressionMIMETypes(
   String[] names
   String[][] values
```

)

removeCompressionMIMETypesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError

For each named virtual server, remove new MIME types from the list of types to compress. This is a location specific function, any action will operate on the specified location.

```
void removeCompressionMIMETypesByLocation(
   String location
   String[] names
   String[][] values
)
```

removeFTPPortRange(names) throws ObjectDoesNotExist, DeploymentError

Allow FTP connections to use any free ports, for each of the named virtual servers.

```
void removeFTPPortRange(
   String[] names
)
```

removeFTPPortRangeByLocation(location, names) throws ObjectDoesNotExist, DeploymentError

Allow FTP connections to use any free ports, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void removeFTPPortRangeByLocation(
   String location
   String[] names
)
```

removeRTSPPortRange(names) throws ObjectDoesNotExist, DeploymentError

Allow any free ports to be used for RTSP connections, for each of the named virtual servers.

```
void removeRTSPPortRange(
   String[] names
)
```

removeRTSPPortRangeByLocation(location, names) throws ObjectDoesNotExist, DeploymentError

Allow any free ports to be used for RTSP connections, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void removeRTSPPortRangeByLocation(
   String location
   String[] names
)
```

removeResponseRules(names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, remove rules from the list that are run on server responses.

```
void removeResponseRules(
   String[] names
   String[][] rules
)
```

removeResponseRulesByLocation(location, names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, remove rules from the list that are run on server responses. This is a location specific function, any action will operate on the specified location.

```
void removeResponseRulesByLocation(
   String location
   String[] names
   String[][] rules
)
```

removeRules(names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, remove rules from the list of rules that are run on client requests.

```
void removeRules(
   String[] names
   String[][] rules
)
```

removeRulesByLocation(location, names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, remove rules from the list of rules that are run on client requests. This is a location specific function, any action will operate on the specified location.

```
void removeRulesByLocation(
   String location
   String[] names
   String[][] rules
)
```

removeSIPPortRange(names) throws ObjectDoesNotExist, DeploymentError

Allow any free ports to be used for SIP connections, for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode.

```
void removeSIPPortRange(
   String[] names
)
```

removeSIPPortRangeByLocation(location, names) throws ObjectDoesNotExist, DeploymentError

Allow any free ports to be used for SIP connections, for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode. This is a location specific function, any action will operate on the specified location.

```
void removeSIPPortRangeByLocation(
   String location
   String[] names
)
```

removeSSLClientCertificateAuthorities(names, values) throws ObjectDoesNotExist, DeploymentError

Remove certificate authorities for validating client certificates for each of the named virtual servers.

```
void removeSSLClientCertificateAuthorities(
   String[] names
   String[][] values
)
```

removeSSLClientCertificateAuthoritiesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError

Remove certificate authorities for validating client certificates for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void removeSSLClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

removeSSLNeverExpiringClientCertificateAuthorities(names, values) throws ObjectDoesNotExist, DeploymentError

Remove CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed, for each of the named virtual servers.

```
void removeSSLNeverExpiringClientCertificateAuthorities(
   String[] names
   String[][] values
)
```

removeSSLNeverExpiringClientCertificateAuthoritiesByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError

Remove CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void removeSSLNeverExpiringClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

renameVirtualServer(names, new_names) throws ObjectDoesNotExist, InvalidObjectName, DeploymentError, InvalidOperation

Rename each of the named virtual servers.

```
void renameVirtualServer(
   String[] names
   String[] new_names
)
```

setAddClusterClientIPHeader(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether a 'X-Cluster-Client-Ip' header should be added to each HTTP request, for each of the named virtual servers. The 'X-Cluster-Client-Ip' header contains the client's IP address.

```
void setAddClusterClientIPHeader(
   String[] names
   Boolean[] values
)
```

setAddClusterClientIPHeaderByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether a 'X-Cluster-Client-Ip' header should be added to each HTTP request, for each of the named virtual servers. The 'X-Cluster-Client-Ip' header contains the client's IP address. This is a location specific function, any action will operate on the specified location.

```
void setAddClusterClientIPHeaderByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setApplicationFirewallEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation

For each of the named virtual servers, enable or disable the Zeus Application Firewall Module.

```
void setApplicationFirewallEnabled(
   String[] names
   Boolean[] values
)
```

setApplicationFirewallEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation

For each of the named virtual servers, enable or disable the Zeus Application Firewall Module. This is a location specific function, any action will operate on the specified location.

```
void setApplicationFirewallEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setBandwidthClass(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Bandwidth Class that each of the named virtual servers uses.

```
void setBandwidthClass(
   String[] names
   String[] values
)
```

setBandwidthClassByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Bandwidth Class that each of the named virtual servers uses. This is a location specific function, any action will operate on the specified location.

```
void setBandwidthClassByLocation(
   String location
   String[] names
   String[] values
)
```

setCompressUnknownSize(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should compress documents with no given size.

```
void setCompressUnknownSize(
   String[] names
   Boolean[] values
)
```

setCompressUnknownSizeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should compress documents with no given size. This is a location specific function, any action will operate on the specified location.

```
void setCompressUnknownSizeByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setCompressionEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should compress web pages before sending to the client.

```
void setCompressionEnabled(
   String[] names
   Boolean[] values
)
```

setCompressionEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should compress web pages before sending to the client. This is a location specific function, any action will operate on the specified location.

```
void setCompressionEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setCompressionLevel(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the gzip compression level, for each of the named virtual servers.

```
void setCompressionLevel(
   String[] names
   Unsigned Integer[] values
)
```

setCompressionLevelByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the gzip compression level, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setCompressionLevelByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setCompressionMIMETypes(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the list of MIME types to compress, for each of the named virtual servers.

```
void setCompressionMIMETypes(
   String[] names
   String[][] values
)
```

setCompressionMIMETypesByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the list of MIME types to compress, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setCompressionMIMETypesByLocation(
   String location
   String[] names
   String[][] values
)
```

setCompressionMaxSize(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the maximum document size to compress, in bytes, for each of the named virtual servers. A document size of '0' means 'unlimited'.

```
void setCompressionMaxSize(
   String[] names
   Unsigned Integer[] values
)
```

setCompressionMaxSizeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the maximum document size to compress, in bytes, for each of the named virtual servers. A document size of '0' means 'unlimited'. This is a location specific function, any action will operate on the specified location.

```
void setCompressionMaxSizeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setCompressionMinSize(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the minimum document size to compress, in bytes, for each of the named virtual servers.

```
void setCompressionMinSize(
   String[] names
   Unsigned Integer[] values
)
```

setCompressionMinSizeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the minimum document size to compress, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setCompressionMinSizeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setConnectTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time to wait for data from a new connection, in seconds, for each of the named virtual servers. If no data is received in this time, the connection will be closed.

```
void setConnectTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setConnectTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time to wait for data from a new connection, in seconds, for each of the named virtual servers. If no data is received in this time, the connection will be closed. This is a location specific function, any action will operate on the specified location.

```
void setConnectTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setCookieDomainRewriteMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set how each of the named virtual servers should rewrite the domain portion of cookies set by a back-end web server.

```
void setCookieDomainRewriteMode(
   String[] names
   VirtualServer.CookieDomainRewriteMode[] values
)
```

setCookieDomainRewriteModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set how each of the named virtual servers should rewrite the domain portion of cookies set by a back-end web server. This is a location specific function, any action will operate on the specified location.

```
void setCookieDomainRewriteModeByLocation(
   String location
   String[] names
   VirtualServer.CookieDomainRewriteMode[] values
)
```

setCookieNamedDomain(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the domain to use when rewriting cookie domains, for each of the named virtual servers.

```
void setCookieNamedDomain(
   String[] names
   String[] values
)
```

setCookieNamedDomainByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the domain to use when rewriting cookie domains, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setCookieNamedDomainByLocation(
   String location
   String[] names
   String[] values
)
```

setCookiePathRewrite(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set the regex, and replacement for rewriting the path portion of a cookie.

```
void setCookiePathRewrite(
   String[] names
   VirtualServer.RegexReplacement[] values
)
```

setCookiePathRewriteByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set the regex, and replacement for rewriting the path portion of a cookie. This is a location specific function, any action will operate on the specified location.

```
void setCookiePathRewriteByLocation(
   String location
   String[] names
   VirtualServer.RegexReplacement[] values
)
```

setCookieSecureFlagRewriteMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should modify the 'secure' tag of cookies set by a back-end web server.

```
void setCookieSecureFlagRewriteMode(
   String[] names
   VirtualServer.CookieSecureFlagRewriteMode[] values
)
```

setCookieSecureFlagRewriteModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should modify the 'secure' tag of cookies set by a back-end web server. This is a location specific function, any action will operate on the specified location.

```
void setCookieSecureFlagRewriteModeByLocation(
   String location
   String[] names
   VirtualServer.CookieSecureFlagRewriteMode[] values
)
```

setDefaultPool(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the default Pool that traffic is sent to for each of the named virtual servers.

```
void setDefaultPool(
   String[] names
   String[] values
)
```

setDefaultPoolByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the default Pool that traffic is sent to for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setDefaultPoolByLocation(
   String location
   String[] names
   String[] values
)
```

setEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers is enabled (i.e. serving traffic).

```
void setEnabled(
   String[] names
   Boolean[] values
)
```

setEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers is enabled (i.e. serving traffic). This is a location specific function, any action will operate on the specified location.

```
void setEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setErrorFile(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the file names of the error texts that each of the named virtual servers will send back to a client in case of back-end or internal errors.

```
void setErrorFile(
    String[] names
    String[] values
)
```

setErrorFileByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the file names of the error texts that each of the named virtual servers will send back to a client in case of back-end or internal errors. This is a location specific function, any action will operate on the specified location.

```
void setErrorFileByLocation(
    String location
    String[] names
    String[] values
)
```

setFTPDataSourcePort(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the source port each of the named virtual servers should use for active-mode FTP data connections. If 0, a random high port will be used, otherwise the specified port will be used. If a port below 1024 is required you must first explicitly permit use of low ports with the ftp_data_bind_low global setting.

```
void setFTPDataSourcePort(
    String[] names
    Unsigned Integer[] values
)
```

setFTPDataSourcePortByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the source port each of the named virtual servers should use for active-mode FTP data connections. If 0, a random high port will be used, otherwise the specified port will be used. If a port below 1024 is required you must first explicitly permit use of low ports with the ftp_data_bind_low global setting. This is a location specific function, any action will operate on the specified location.

```
void setFTPDataSourcePortByLocation(
    String location
    String[] names
```

```
        Unsigned Integer[] values
    )
```

setFTPForceClientSecure(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should require incoming FTP data connections (from clients) to originate from the same IP address as the corresponding control connection.

```
    void setFTPForceClientSecure(
        String[] names
        Boolean[] values
    )
```

setFTPForceClientSecureByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should require incoming FTP data connections (from clients) to originate from the same IP address as the corresponding control connection. This is a location specific function, any action will operate on the specified location.

```
    void setFTPForceClientSecureByLocation(
        String location
        String[] names
        Boolean[] values
    )
```

setFTPForceServerSecure(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should require incoming FTP data connections (from nodes) to originate from the same IP address as the corresponding control connection.

```
    void setFTPForceServerSecure(
        String[] names
        Boolean[] values
    )
```

setFTPForceServerSecureByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should require incoming FTP data connections (from nodes) to originate from the same IP address as the corresponding

control connection. This is a location specific function, any action will operate on the specified location.

```
void setFTPForceServerSecureByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setFTPPortRange(names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for FTP data connections for each of the named virtual servers.

```
void setFTPPortRange(
   String[] names
   VirtualServer.FTPPortRange[] range
)
```

setFTPPortRangeByLocation(location, names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for FTP data connections for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setFTPPortRangeByLocation(
   String location
   String[] names
   VirtualServer.FTPPortRange[] range
)
```

setFTPSSLData(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should use SSL on the data connection as well as the control connection

```
void setFTPSSLData(
   String[] names
   Boolean[] values
)
```

setFTPSSLDataByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should use SSL on the data connection as well as the control connection This is a location specific function, any action will operate on the specified location.

```
void setFTPSSLDataByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setKeepalive(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should allow clients to maintain keepalive connections.

```
void setKeepalive(
   String[] names
   Boolean[] values
)
```

setKeepaliveByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should allow clients to maintain keepalive connections. This is a location specific function, any action will operate on the specified location.

```
void setKeepaliveByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setKeepaliveTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time that an idle keepalive connection should be kept open for, in seconds, for each of the named virtual servers.

```
void setKeepaliveTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setKeepaliveTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time that an idle keepalive connection should be kept open for, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setKeepaliveTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setListenAddresses(names, addresses) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the specific IP addresses and hostnames for each named virtual server to listen on.

```
void setListenAddresses(
   String[] names
   String[][] addresses
)
```

setListenAddressesByLocation(location, names, addresses) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the specific IP addresses and hostnames for each named virtual server to listen on. This is a location specific function, any action will operate on the specified location.

```
void setListenAddressesByLocation(
   String location
   String[] names
   String[][] addresses
)
```

setListenOnAllAddresses(names) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Make each of the named virtual servers listen on all IP addresses.

```
void setListenOnAllAddresses(
   String[] names
)
```

setListenOnAllAddressesByLocation(location, names) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Make each of the named virtual servers listen on all IP addresses. This is a location specific function, any action will operate on the specified location.

```
void setListenOnAllAddressesByLocation(
   String location
   String[] names
)
```

setListenTrafficIPGroups(names, groups) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set specific Traffic IP Groups for it to listen on.

```
void setListenTrafficIPGroups(
   String[] names
   String[][] groups
)
```

setListenTrafficIPGroupsByLocation(location, names, groups) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set specific Traffic IP Groups for it to listen on. This is a location specific function, any action will operate on the specified location.

```
void setListenTrafficIPGroupsByLocation(
   String location
   String[] names
   String[][] groups
)
```

setLocationDefaultRewriteMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should rewrite the 'Location' header. The rewrite is only performed if the location rewrite regex didn't match.

```
void setLocationDefaultRewriteMode(
   String[] names
   VirtualServer.LocationDefaultRewriteMode[] values
)
```

setLocationDefaultRewriteModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should rewrite the 'Location' header. The rewrite is only performed if the location rewrite regex didn't match. This is a location specific function, any action will operate on the specified location.

```
void setLocationDefaultRewriteModeByLocation(
   String location
   String[] names
   VirtualServer.LocationDefaultRewriteMode[] values
)
```

setLocationRewrite(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set the regex, and replacement for rewriting any 'Location' headers.

```
void setLocationRewrite(
   String[] names
   VirtualServer.RegexReplacement[] values
)
```

setLocationRewriteByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

For each of the named virtual servers, set the regex, and replacement for rewriting any 'Location' headers. This is a location specific function, any action will operate on the specified location.

```
void setLocationRewriteByLocation(
   String location
   String[] names
   VirtualServer.RegexReplacement[] values
)
```

setLogClientConnectionFailures(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log client connection failures.

```
void setLogClientConnectionFailures(
   String[] names
   Boolean[] values
)
```

setLogClientConnectionFailuresByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log client connection failures. This is a location specific function, any action will operate on the specified location.

```
void setLogClientConnectionFailuresByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setLogEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should log each connection to a disk on the file system.

```
void setLogEnabled(
   String[] names
   Boolean[] values
)
```

setLogEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should log each connection to a disk on the file system. This is a location specific function, any action will operate on the specified location.

```
void setLogEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setLogFilename(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the name of the file used to store request logs, for each of the named virtual servers.

```
void setLogFilename(
   String[] names
   String[] values
)
```

setLogFilenameByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the name of the file used to store request logs, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setLogFilenameByLocation(
   String location
   String[] names
   String[] values
)
```

setLogFormat(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the log file format for each of the named virtual servers.

```
void setLogFormat(
   String[] names
   String[] values
)
```

setLogFormatByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the log file format for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setLogFormatByLocation(
   String location
   String[] names
   String[] values
)
```

setLogSSLFailures(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log ssl failures.

```
void setLogSSLFailures(
   String[] names
   Boolean[] values
)
```

setLogSSLFailuresByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log ssl failures. This is a location specific function, any action will operate on the specified location.

```
void setLogSSLFailuresByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setLogServerConnectionFailures(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log server connection failures.

```
void setLogServerConnectionFailures(
   String[] names
   Boolean[] values
)
```

setLogServerConnectionFailuresByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the virtual server will log server connection failures. This is a location specific function, any action will operate on the specified location.

```
void setLogServerConnectionFailuresByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setMIMEAutoDetect(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should auto-detect MIME types if the server does not provide them.

```
void setMIMEAutoDetect(
   String[] names
   Boolean[] values
)
```

setMIMEAutoDetectByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should auto-detect MIME types if the server does not provide them. This is a location specific function, any action will operate on the specified location.

```
void setMIMEAutoDetectByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setMIMEDefaultType(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the MIME type that the server uses as its 'default', for each of the named virtual servers. Responses with this mime type will be auto-corrected by the virtual server if this setting is enabled.

```
void setMIMEDefaultType(
   String[] names
   String[] values
)
```

setMIMEDefaultTypeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the MIME type that the server uses as its 'default', for each of the named virtual servers. Responses with this mime type will be auto-corrected by the virtual server if this setting is enabled. This is a location specific function, any action will operate on the specified location.

```
void setMIMEDefaultTypeByLocation(
   String location
   String[] names
   String[] values
)
```

setMaxClientBuffer(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the amount of memory used to store data sent by the client, in bytes, for each of the named virtual servers.

```
void setMaxClientBuffer(
   String[] names
   Unsigned Integer[] values
)
```

setMaxClientBufferByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the amount of memory used to store data sent by the client, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setMaxClientBufferByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxServerBuffer(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the amount of memory used to store data returned by the server, in bytes, for each of the named virtual servers.

```
void setMaxServerBuffer(
   String[] names
   Unsigned Integer[] values
)
```

setMaxServerBufferByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the amount of memory used to store data returned by the server, in bytes, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setMaxServerBufferByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setNote(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the note for each of the named virtual servers.

```
void setNote(
   String[] names
   String[] values
)
```

setPort(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port that each of the named virtual servers listens on for incoming connections.

```
void setPort(
   String[] names
   Unsigned Integer[] values
)
```

setPortByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port that each of the named virtual servers listens on for incoming connections. This is a location specific function, any action will operate on the specified location.

```
void setPortByLocation(
   String location
   String[] names
   Unsigned Integer[] values
```

```
)
```

setProtection(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Service Protection Settings that are used to protect each of the named virtual servers.

```
void setProtection(
   String[] names
   String[] values
)
```

setProtectionByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Service Protection Settings that are used to protect each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setProtectionByLocation(
   String location
   String[] names
   String[] values
)
```

setProtocol(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the protocol that each of the named virtual servers uses.

```
void setProtocol(
   String[] names
   VirtualServer.Protocol[] values
)
```

setProxyClose(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should send a FIN packet on to the back-end server when it is received from the client. The alternative is to close the connection to the client immediately. If the traffic manager is responding to the request itself, enabling this setting will cause the traffic manager to continue writing the response even after it has received a FIN from the client.

```
void setProxyClose(
   String[] names
   Boolean[] values
```

```
)
```

setProxyCloseByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should send a FIN packet on to the back-end server when it is received from the client. The alternative is to close the connection to the client immediately. If the traffic manager is responding to the request itself, enabling this setting will cause the traffic manager to continue writing the response even after it has received a FIN from the client. This is a location specific function, any action will operate on the specified location.

```
void setProxyCloseByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setRTSPPortRange(names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for RTSP streaming data connections for each of the named virtual servers.

```
void setRTSPPortRange(
   String[] names
   VirtualServer.PortRange[] range
)
```

setRTSPPortRangeByLocation(location, names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for RTSP streaming data connections for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setRTSPPortRangeByLocation(
   String location
   String[] names
   VirtualServer.PortRange[] range
)
```

setRequestSyslogEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should log each connection to a remote syslog server.

```
void setRequestSyslogEnabled(
   String[] names
   Boolean[] values
)
```

setRequestSyslogEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should log each connection to a remote syslog server. This is a location specific function, any action will operate on the specified location.

```
void setRequestSyslogEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setRequestSyslogFormat(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the remote log line format for each of the named virtual servers.

```
void setRequestSyslogFormat(
   String[] names
   String[] values
)
```

setRequestSyslogFormatByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the remote log line format for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setRequestSyslogFormatByLocation(
   String location
   String[] names
   String[] values
)
```

setRequestSyslogIPEndpoint(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the remote syslog endpoint for each of the named virtual servers

```
void setRequestSyslogIPEndpoint(
   String[] names
   String[] values
```

)

setRequestSyslogIPEndpointByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the remote syslog endpoint for each of the named virtual servers This is a location specific function, any action will operate on the specified location.

```
void setRequestSyslogIPEndpointByLocation(
   String location
   String[] names
   String[] values
)
```

setRequestTracingEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to record a detailed list of processing history for each request.

```
void setRequestTracingEnabled(
   String[] names
   Boolean[] values
)
```

setRequestTracingEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to record a detailed list of processing history for each request. This is a location specific function, any action will operate on the specified location.

```
void setRequestTracingEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setRequestTracingIO(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to record a detailed list of every IO event in the processing history for each request.

```
void setRequestTracingIO(
   String[] names
   Boolean[] values
)
```

setRequestTracingIOByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to record a detailed list of every IO event in the processing history for each request. This is a location specific function, any action will operate on the specified location.

```
void setRequestTracingIOByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setResponseRules(names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the rules that are run on server responses for each of the named virtual servers.

```
void setResponseRules(
   String[] names
   VirtualServer.Rule[][] rules
)
```

setResponseRulesByLocation(location, names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the rules that are run on server responses for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setResponseRulesByLocation(
   String location
   String[] names
   VirtualServer.Rule[][] rules
)
```

setRewriteSIPURI(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the Request-URI of SIP requests will be replaced with the selected back-end node's address.

```
void setRewriteSIPURI(
   String[] names
   Boolean[] values
)
```

setRewriteSIPURIByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether the Request-URI of SIP requests will be replaced with the selected back-end node's address. This is a location specific function, any action will operate on the specified location.

```
void setRewriteSIPURIByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setRules(names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the rules that are run on client requests for each of the named virtual servers.

```
void setRules(
   String[] names
   VirtualServer.Rule[][] rules
)
```

setRulesByLocation(location, names, rules) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the rules that are run on client requests for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setRulesByLocation(
   String location
   String[] names
   VirtualServer.Rule[][] rules
)
```

setSIPDangerousRequestMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set what should be done with requests that contain body data and should be routed to an external IP.

```
void setSIPDangerousRequestMode(
   String[] names
   VirtualServer.SIPDangerousRequestMode[] values
)
```

setSIPDangerousRequestModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set what should be done with requests that contain body data and should be routed to an external IP. This is a location specific function, any action will operate on the specified location.

```
void setSIPDangerousRequestModeByLocation(
   String location
   String[] names
   VirtualServer.SIPDangerousRequestMode[] values
)
```

setSIPFollowRoute(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to follow routing information in SIP requests.

```
void setSIPFollowRoute(
   String[] names
   Boolean[] values
)
```

setSIPFollowRouteByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether to follow routing information in SIP requests. This is a location specific function, any action will operate on the specified location.

```
void setSIPFollowRouteByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSIPMaxConnectionMemory(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set maximum memory per connection.

```
void setSIPMaxConnectionMemory(
   String[] names
   Unsigned Integer[] values
)
```

setSIPMaxConnectionMemoryByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set maximum memory per connection. This is a location specific function, any action will operate on the specified location.

```
void setSIPMaxConnectionMemoryByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setSIPMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set which mode of operation the SIP virtual server should run in.

```
void setSIPMode(
    String[] names
    VirtualServer.SIPMode[] values
)
```

setSIPModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set which mode of operation the SIP virtual server should run in. This is a location specific function, any action will operate on the specified location.

```
void setSIPModeByLocation(
    String location
    String[] names
    VirtualServer.SIPMode[] values
)
```

setSIPPortRange(names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for SIP data connections for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode.

```
void setSIPPortRange(
    String[] names
    VirtualServer.PortRange[] range
)
```

setSIPPortRangeByLocation(location, names, range) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the port range used for SIP data connections for each of the named virtual servers. This setting is only used when the SIP virtual server is using 'Full Gateway' mode. This is a location specific function, any action will operate on the specified location.

```
void setSIPPortRangeByLocation(
   String location
   String[] names
   VirtualServer.PortRange[] range
)
```

setSIPStreamingTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time, in seconds, after which a UDP stream will timeout if it has not seen any data.

```
void setSIPStreamingTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setSIPStreamingTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time, in seconds, after which a UDP stream will timeout if it has not seen any data. This is a location specific function, any action will operate on the specified location.

```
void setSIPStreamingTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setSSLCertificate(names, certs) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the name of the default SSL Certificate that is used for SSL decryption for each of the named virtual servers. This is the name of an item in the SSL Certificates Catalog. You must call this function to set an SSL Certificate before turning on SSL Decryption.

```
void setSSLCertificate(
   String[] names
   String[] certs
)
```

setSSLCertificateByLocation(location, names, certs) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the name of the default SSL Certificate that is used for SSL decryption for each of the named virtual servers. This is the name of an item in the SSL Certificates Catalog. You must call this function to set an SSL Certificate before turning on SSL Decryption. This is a location specific function, any action will operate on the specified location.

```
void setSSLCertificateByLocation(
   String location
   String[] names
   String[] certs
)
```

setSSLClientCertificateAuthorities(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the certificate authorities that are trusted for validating client certificates, for each of the named virtual servers.

```
void setSSLClientCertificateAuthorities(
   String[] names
   String[][] values
)
```

setSSLClientCertificateAuthoritiesByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the certificate authorities that are trusted for validating client certificates, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setSSLClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

setSSLClientCertificateHeaders(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should add HTTP headers to each request to show the data in the client certificate.

```
void setSSLClientCertificateHeaders(
   String[] names
   VirtualServer.SSLClientCertificateHeaders[] values
)
```

setSSLClientCertificateHeadersByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should add HTTP headers to each request to show the data in the client certificate. This is a location specific function, any action will operate on the specified location.

```
void setSSLClientCertificateHeadersByLocation(
   String location
   String[] names
   VirtualServer.SSLClientCertificateHeaders[] values
)
```

setSSLDecrypt(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Sets whether each of the named virtual servers should decrypt SSL traffic. This function will error unless an SSL Certificate has previously been set using setSSLCertificate.

```
void setSSLDecrypt(
   String[] names
   Boolean[] values
)
```

setSSLDecryptByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Sets whether each of the named virtual servers should decrypt SSL traffic. This function will error unless an SSL Certificate has previously been set using setSSLCertificate. This is a location specific function, any action will operate on the specified location.

```
void setSSLDecryptByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLExpectStartTLS(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should upgrade SMTP connections to SSL using the STARTTLS command.

```
void setSSLExpectStartTLS(
   String[] names
   Boolean[] values
)
```

setSSLExpectStartTLSByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should upgrade SMTP connections to SSL using the STARTTLS command. This is a location specific function, any action will operate on the specified location.

```
void setSSLExpectStartTLSByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLHeaders(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should add HTTP headers to each request to show SSL connection parameters.

```
void setSSLHeaders(
   String[] names
   Boolean[] values
)
```

setSSLHeadersByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should add HTTP headers to each request to show SSL connection parameters. This is a location specific function, any action will operate on the specified location.

```
void setSSLHeadersByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLLogEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

This method is now obsolete. SSL logging is now done if LogConnectionFailures is enabled. Use VirtualServer.getLogConnectionFailures and VirtualServer.getLogConnection failures to control this configuration.

```
void setSSLLogEnabled(
   String[] names
   Boolean[] values
)
```

setSSLNeverExpiringClientCertificateAuthorities(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed.

```
void setSSLNeverExpiringClientCertificateAuthorities(
   String[] names
   String[][] values
)
```

setSSLNeverExpiringClientCertificateAuthoritiesByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the CAs for which any client certificate they validate is considered valid even if the client certificate's expiration date has passed. This is a location specific function, any action will operate on the specified location.

```
void setSSLNeverExpiringClientCertificateAuthoritiesByLocation(
   String location
   String[] names
   String[][] values
)
```

setSSLRequestClientCertMode(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should request (or require) an identifying certificate from each client.

```
void setSSLRequestClientCertMode(
   String[] names
   VirtualServer.SSLRequestClientCertMode[] values
)
```

setSSLRequestClientCertModeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should request (or require) an identifying certificate from each client. This is a location specific function, any action will operate on the specified location.

```
void setSSLRequestClientCertModeByLocation(
   String location
   String[] names
   VirtualServer.SSLRequestClientCertMode[] values
)
```

setSSLSendCloseAlerts(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should send a close alert when initiating SSL socket disconnections.

```
void setSSLSendCloseAlerts(
   String[] names
   Boolean[] values
)
```

setSSLSendCloseAlertsByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should send a close alert when initiating SSL socket disconnections. This is a location specific function, any action will operate on the specified location.

```
void setSSLSendCloseAlertsByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLTrustMagic(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should decode extra information on the true origin of an SSL connection. This information is prefixed onto an incoming SSL connection from another traffic manager.

```
void setSSLTrustMagic(
   String[] names
   Boolean[] values
)
```

setSSLTrustMagicByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should decode extra information on the true origin of an SSL connection. This information is prefixed onto an incoming SSL connection from another traffic manager. This is a location specific function, any action will operate on the specified location.

```
void setSSLTrustMagicByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setServerfirstBanner(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the banner that each of the named virtual servers sends to clients for server-first protocols such as POP, SMTP and IMAP.

```
void setServerfirstBanner(
   String[] names
   String[] values
)
```

setServerfirstBannerByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the banner that each of the named virtual servers sends to clients for server-first protocols such as POP, SMTP and IMAP. This is a location specific function, any action will operate on the specified location.

```
void setServerfirstBannerByLocation(
   String location
   String[] names
   String[] values
)
```

setServiceLevelMonitoring(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Service Level Monitoring class that each of the named virtual servers uses.

```
void setServiceLevelMonitoring(
   String[] names
   String[] values
)
```

setServiceLevelMonitoringByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Service Level Monitoring class that each of the named virtual servers uses. This is a location specific function, any action will operate on the specified location.

```
void setServiceLevelMonitoringByLocation(
   String location
   String[] names
   String[] values
)
```

setSipTransactionTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time after which an incomplete transaction should be discarded, in seconds, for each of the named virtual servers.

```
void setSipTransactionTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setSipTransactionTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time after which an incomplete transaction should be discarded, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setSipTransactionTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time to wait for data on an already established connection, in seconds, for each of the named virtual servers.

```
void setTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time to wait for data on an already established connection, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setUDPResponseDatagramsExpected(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the expected number of UDP datagrams in the response, for each of the named virtual servers. For simple request/response protocols a value of '1' should be used. If set to -1, the connection will not be discarded until the udp_timeout is reached.

```
void setUDPResponseDatagramsExpected(
   String[] names
   Integer[] values
)
```

setUDPResponseDatagramsExpectedByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the expected number of UDP datagrams in the response, for each of the named virtual servers. For simple request/response protocols a value of '1' should be used. If set to -1, the connection will not be discarded until the udp_timeout is reached. This is a location specific function, any action will operate on the specified location.

```
void setUDPResponseDatagramsExpectedByLocation(
   String location
   String[] names
   Integer[] values
)
```

setUDPTimeout(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time after which an idle UDP connection should be discarded and resources reclaimed, in seconds, for each of the named virtual servers.

```
void setUDPTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setUDPTimeoutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time after which an idle UDP connection should be discarded and resources reclaimed, in seconds, for each of the named virtual servers. This is a location specific function, any action will operate on the specified location.

```
void setUDPTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setUseNagle(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether Nagle's algorithm should be used for TCP connections.

```
void setUseNagle(
   String[] names
   Boolean[] values
)
```

setUseNagleByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether Nagle's algorithm should be used for TCP connections. This is a location specific function, any action will operate on the specified location.

```
void setUseNagleByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setWebcacheControlOut(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Cache-Control header that should be sent with cached HTTP responses.

```
void setWebcacheControlOut(
   String[] names
   String[] values
)
```

setWebcacheControlOutByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the Cache-Control header that should be sent with cached HTTP responses. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheControlOutByLocation(
   String location
   String[] names
   String[] values
)
```

setWebcacheEnabled(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should attempt to cache web server responses.

```
void setWebcacheEnabled(
   String[] names
   Boolean[] values
)
```

setWebcacheEnabledByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set whether each of the named virtual servers should attempt to cache web server responses. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setWebcacheErrorpageTime(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should cache error pages for.

```
void setWebcacheErrorpageTime(
   String[] names
   Unsigned Integer[] values
)
```

setWebcacheErrorpageTimeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should cache error pages for. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheErrorpageTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setWebcacheRefreshTime(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should consider re-fetching cached pages in.

```
void setWebcacheRefreshTime(
   String[] names
   Unsigned Integer[] values
)
```

setWebcacheRefreshTimeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should consider re-fetching cached pages in. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheRefreshTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setWebcacheTime(names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should cache web pages for.

```
void setWebcacheTime(
   String[] names
   Unsigned Integer[] values
)
```

setWebcacheTimeByLocation(location, names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the time periods that each of the named virtual servers should cache web pages for. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

6.2.2 Structures

VirtualServer.BasicInfo

This structure contains the basic information for a virtual server. It is used when creating a server, or modifying the port, protocol or default pool of a server.

```
struct VirtualServer.BasicInfo {
    # The port to listen for incoming connections on.
    Integer port;

    # The protocol that this virtual server handles.
    VirtualServer.Protocol protocol;

    # The default pool that traffic to this virtual server will go
    # to.
    String default_pool;
}
```

VirtualServer.FTPPortRange

This structure contains the range of ports that FTP data connections use.

```
struct VirtualServer.FTPPortRange {
    # The lower bound of the port range for FTP data connections.
    Integer low;

    # The upper bound of the port range for FTP data connections.
    Integer high;
}
```

VirtualServer.PortRange

This structure contains the range of ports.

```
struct VirtualServer.PortRange {
    # The lower bound of the port range.
    Integer low;

    # The upper bound of the port range.
    Integer high;
}
```

VirtualServer.RegexReplacement

This structure contains a regex and a replacement string.

```
struct VirtualServer.RegexReplacement {
    # The regular expression used to match against.
    String regex;
```

```
    # The replacement string if the regular expression matches.
    # Parameters $1-$9 can be used to represent bracketed parts of
    # the regular expression.
    String replacement;
}
```

VirtualServer.Rule

This structure contains the information on how a rule is assigned to a virtual server.

```
struct VirtualServer.Rule {
    # The name of the rule.
    String name;

    # Whether the rule is enabled or not.
    Boolean enabled;

    # Whether the rule runs on every request/response, or just the
    # first
    VirtualServer.RuleRunFlag run_frequency;
}
```

VirtualServer.SSLSite

This object represents a mapping between a destination address and an SSL certificate (this is the name of an item in the SSL Certificates Catalog). Clients connecting to the SSL Site's address will be sent the associated certificate.

```
struct VirtualServer.SSLSite {
    # The destination address that this site handles.
    String dest_address;

    # The certificate that will be sent when clients connect to
    # the destination address. This is a certificate name from the
    # SSL Certificates Catalog.
    String certificate;
}
```

6.2.3 Enumerations

VirtualServer.CookieDomainRewriteMode

```
enum VirtualServer.CookieDomainRewriteMode {
    # Do not rewrite the domain
    no_rewrite,

    # Rewrite the domain to the host header of the request
    set_to_request,
```

```
        # Rewrite the domain to the named domain value
        set_to_named
    }
```

VirtualServer.CookieSecureFlagRewriteMode

```
enum VirtualServer.CookieSecureFlagRewriteMode {
    # Do not modify the 'secure' tag
    no_modify,

    # Set the 'secure' tag
    set_secure,

    # Unset the 'secure' tag
    unset_secure
}
```

VirtualServer.LocationDefaultRewriteMode

```
enum VirtualServer.LocationDefaultRewriteMode {
    # Nothing;
    never,

    # Rewrite the hostname to the request's "Host" header, and
    # rewrite the protocol and port if necessary;
    always,

    # Do not rewrite the hostname. Rewrite the protocol and port
    # if the hostname matches the request's "Host" header.
    if_host_matches
}
```

VirtualServer.Protocol

```
enum VirtualServer.Protocol {
    # HTTP
    http,

    # FTP
    ftp,

    # IMAPv2
    imapv2,

    # IMAPv3
    imapv3,

    # IMAPv4
```

```
        imapv4,

        # POP3
        pop3,

        # SMTP
        smtp,

        # LDAP
        ldap,

        # Telnet
        telnet,

        # SSL
        ssl,

        # SSL (HTTPS)
        https,

        # SSL (IMAPS)
        imaps,

        # SSL (POP3S)
        pop3s,

        # SSL (LDAPS)
        ldaps,

        # UDP - Streaming
        udpstreaming,

        # UDP
        udp,

        # DNS (UDP)
        dns,

        # DNS (TCP)
        dns_tcp,

        # SIP (UDP)
        sipudp,

        # SIP (TCP)
        siptcp,

        # RTSP
        rtsp,

        # Generic server first
```

```
    server_first,

    # Generic client first
    client_first
}
```

VirtualServer.RuleRunFlag

This enumeration defines the run flags for a particular rule.

```
enum VirtualServer.RuleRunFlag {
    # Run on every request or response.
    run_every,

    # Run only on the first request or response.
    only_first
}
```

VirtualServer.SIPDangerousRequestMode

```
enum VirtualServer.SIPDangerousRequestMode {
    # Send the request to a back-end node
    node,

    # Send a 403 Forbidden response to the client
    forbid,

    # Forward the request to its target URI (dangerous)
    forward
}
```

VirtualServer.SIPMode

```
enum VirtualServer.SIPMode {
    # SIP Routing
    route,

    # SIP Gateway
    sipgw,

    # Full Gateway
    fullgw
}
```

VirtualServer.SSLClientCertificateHeaders

```
enum VirtualServer.SSLClientCertificateHeaders {
    # No data
    none,
```

```
        # Certificate fields
        simple,

        # Certificate fields and certificate text
        all
    }
```

VirtualServer.SSLRequestClientCertMode

```
enum VirtualServer.SSLRequestClientCertMode {
    # Do not request a client certificate
    dont_request,

    # Request, but do not require a client certificate
    request,

    # Require a client certificate
    require
}
```

6.3   Pool

URI: `http://soap.zeus.com/zxtm/1.0/Pool/`

The Pool interface allows management of Pool objects. Using this interface, you can create, delete and rename pool objects, and manage their configuration.

6.3.1   Methods

addAutoScaledPool(names, nodes) throws ObjectAlreadyExists, InvalidObjectName, InvalidInput, DeploymentError

Add each of the named auto-scaled pools, using the node lists for each. The node lists can be empty

```
void addAutoScaledPool(
    String[] names
    String[][] nodes
)
```

addDrainingNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Add nodes to the lists of draining nodes, for each of the named pools.

```
void addDrainingNodes(
    String[] names
```

```
   String[][] values
)
```

addDrainingNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Add nodes to the lists of draining nodes, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void addDrainingNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

addMonitors(names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Add monitors to each of the named pools.

```
void addMonitors(
   String[] names
   String[][] values
)
```

addMonitorsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Add monitors to each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void addMonitorsByLocation(
   String location
   String[] names
   String[][] values
)
```

addNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Add nodes to each of the named pools.

```
void addNodes(
   String[] names
   String[][] values
)
```

addNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Add nodes to each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void addNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

addPool(names, nodes) throws ObjectAlreadyExists, InvalidObjectName, InvalidInput, DeploymentError

Add each of the named pools, using the node lists for each.

```
void addPool(
   String[] names
   String[][] nodes
)
```

copyPool(names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError

Copy each of the named pools.

```
void copyPool(
   String[] names
   String[] new_names
)
```

deletePool(names) throws ObjectInUse, ObjectDoesNotExist, DeploymentError

Delete each of the named pools.

```
void deletePool(
   String[] names
)
```

disableNodes(names, nodes) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

For each of the named pools, disable the specified nodes in the pool.

```
void disableNodes(
   String[] names
   String[][] nodes
```

```
)
```

disableNodesByLocation(location, names, nodes) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

For each of the named pools, disable the specified nodes in the pool. This is a location specific function, any action will operate on the specified location.

```
void disableNodesByLocation(
   String location
   String[] names
   String[][] nodes
)
```

enableNodes(names, nodes) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

For each of the named pools, enable the specified nodes that are disabled in the pool.

```
void enableNodes(
   String[] names
   String[][] nodes
)
```

enableNodesByLocation(location, names, nodes) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

For each of the named pools, enable the specified nodes that are disabled in the pool. This is a location specific function, any action will operate on the specified location.

```
void enableNodesByLocation(
   String location
   String[] names
   String[][] nodes
)
```

getAutoscaleCloudcredentials(names) throws ObjectDoesNotExist

Get the cloud credentials for this auto-scaled pool

```
String[] getAutoscaleCloudcredentials(
   String[] names
)
```

getAutoscaleCloudcredentialsByLocation(location, names) throws ObjectDoesNotExist

Get the cloud credentials for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
String[] getAutoscaleCloudcredentialsByLocation(
   String location
   String[] names
)
```

getAutoscaleEnabled(names) throws ObjectDoesNotExist

Get whether this pool uses auto-scaling.

```
Boolean[] getAutoscaleEnabled(
   String[] names
)
```

getAutoscaleEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether this pool uses auto-scaling. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getAutoscaleEnabledByLocation(
   String location
   String[] names
)
```

getAutoscaleExternal(names) throws ObjectDoesNotExist

Get whether autoscaling is handled externally or internally

```
Boolean[] getAutoscaleExternal(
   String[] names
)
```

getAutoscaleExternalByLocation(location, names) throws ObjectDoesNotExist

Get whether autoscaling is handled externally or internally This is a location specific function, any action will operate on the specified location.

```
Boolean[] getAutoscaleExternalByLocation(
   String location
   String[] names
)
```

getAutoscaleHysteresis(names) throws ObjectDoesNotExist

Get the hysteresis period for an auto-scaled pool

```
Unsigned Integer[] getAutoscaleHysteresis(
   String[] names
)
```

getAutoscaleHysteresisByLocation(location, names) throws ObjectDoesNotExist

Get the hysteresis period for an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleHysteresisByLocation(
   String location
   String[] names
)
```

getAutoscaleImageid(names) throws ObjectDoesNotExist

Get the image identifier

```
String[] getAutoscaleImageid(
   String[] names
)
```

getAutoscaleImageidByLocation(location, names) throws ObjectDoesNotExist

Get the image identifier This is a location specific function, any action will operate on the specified location.

```
String[] getAutoscaleImageidByLocation(
   String location
   String[] names
)
```

getAutoscaleIpstouse(names) throws ObjectDoesNotExist

Get whether to use the public or private IPs

```
Pool.AutoscaleIpstouse[] getAutoscaleIpstouse(
   String[] names
)
```

getAutoscaleIpstouseByLocation(location, names) throws ObjectDoesNotExist

Get whether to use the public or private IPs This is a location specific function, any action will operate on the specified location.

```
Pool.AutoscaleIpstouse[] getAutoscaleIpstouseByLocation(
   String location
   String[] names
)
```

getAutoscaleMaxNodes(names) throws ObjectDoesNotExist

Get the maximum number of nodes in an auto-scaled pool

```
Unsigned Integer[] getAutoscaleMaxNodes(
   String[] names
)
```

getAutoscaleMaxNodesByLocation(location, names) throws ObjectDoesNotExist

Get the maximum number of nodes in an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleMaxNodesByLocation(
   String location
   String[] names
)
```

getAutoscaleMinNodes(names) throws ObjectDoesNotExist

Get the minimum number of nodes in an auto-scaled pool

```
Unsigned Integer[] getAutoscaleMinNodes(
   String[] names
)
```

getAutoscaleMinNodesByLocation(location, names) throws ObjectDoesNotExist

Get the minimum number of nodes in an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleMinNodesByLocation(
   String location
   String[] names
)
```

getAutoscaleName(names) throws ObjectDoesNotExist

Get the node name prefix for this auto-scaled pool

```
String[] getAutoscaleName(
```

```
   String[] names
)
```

getAutoscaleNameByLocation(location, names) throws ObjectDoesNotExist

Get the node name prefix for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
String[] getAutoscaleNameByLocation(
   String location
   String[] names
)
```

getAutoscalePort(names) throws ObjectDoesNotExist

Get the port number for this auto-scaled pool

```
Unsigned Integer[] getAutoscalePort(
   String[] names
)
```

getAutoscalePortByLocation(location, names) throws ObjectDoesNotExist

Get the port number for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscalePortByLocation(
   String location
   String[] names
)
```

getAutoscaleRefractory(names) throws ObjectDoesNotExist

Get the refractory period for an auto-scaled pool

```
Unsigned Integer[] getAutoscaleRefractory(
   String[] names
)
```

getAutoscaleRefractoryByLocation(location, names) throws ObjectDoesNotExist

Get the refractory period for an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleRefractoryByLocation(
   String location
   String[] names
)
```

getAutoscaleResponseTime(names) throws ObjectDoesNotExist

Get the expected node response time in milliseconds

```
Unsigned Integer[] getAutoscaleResponseTime(
    String[] names
)
```

getAutoscaleResponseTimeByLocation(location, names) throws ObjectDoesNotExist

Get the expected node response time in milliseconds This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleResponseTimeByLocation(
    String location
    String[] names
)
```

getAutoscaleScaledownLevel(names) throws ObjectDoesNotExist

Get the threshold of conforming requests for scaling down

```
Unsigned Integer[] getAutoscaleScaledownLevel(
    String[] names
)
```

getAutoscaleScaledownLevelByLocation(location, names) throws ObjectDoesNotExist

Get the threshold of conforming requests for scaling down This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleScaledownLevelByLocation(
    String location
    String[] names
)
```

getAutoscaleScaleupLevel(names) throws ObjectDoesNotExist

Get the acceptable lower percentage of conforming requests

```
Unsigned Integer[] getAutoscaleScaleupLevel(
    String[] names
)
```

getAutoscaleScaleupLevelByLocation(location, names) throws ObjectDoesNotExist

Get the acceptable lower percentage of conforming requests This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getAutoscaleScaleupLevelByLocation(
   String location
   String[] names
)
```

getAutoscaleSizeid(names) throws ObjectDoesNotExist

Get the size identifier

```
String[] getAutoscaleSizeid(
   String[] names
)
```

getAutoscaleSizeidByLocation(location, names) throws ObjectDoesNotExist

Get the size identifier This is a location specific function, any action will operate on the specified location.

```
String[] getAutoscaleSizeidByLocation(
   String location
   String[] names
)
```

getBandwidthClass(names) throws ObjectDoesNotExist

Get the Bandwidth Classes that each of the named pools uses.

```
String[] getBandwidthClass(
   String[] names
)
```

getBandwidthClassByLocation(location, names) throws ObjectDoesNotExist

Get the Bandwidth Classes that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
String[] getBandwidthClassByLocation(
   String location
   String[] names
)
```

getDisabledNodes(names) throws ObjectDoesNotExist

For each of the named pools, get the disabled nodes in the pool.

```
String[][] getDisabledNodes(
   String[] names
)
```

getDisabledNodesByLocation(location, names) throws ObjectDoesNotExist

For each of the named pools, get the disabled nodes in the pool. This is a location specific function, any action will operate on the specified location.

```
String[][] getDisabledNodesByLocation(
   String location
   String[] names
)
```

getDrainingNodes(names) throws ObjectDoesNotExist

Get the lists of draining nodes for each of the named pools.

```
String[][] getDrainingNodes(
   String[] names
)
```

getDrainingNodesByLocation(location, names) throws ObjectDoesNotExist

Get the lists of draining nodes for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
String[][] getDrainingNodesByLocation(
   String location
   String[] names
)
```

getErrorFile(names) throws ObjectDoesNotExist

This method is now obsolete and is replaced by VirtualServer.getErrorFile.

```
String[] getErrorFile(
   String[] names
)
```

getFTPSupportRfc2428(names) throws ObjectDoesNotExist

Get whether backend IPv4 nodes understand the FTP EPRT and EPSV commands.

```
Boolean[] getFTPSupportRfc2428(
```

```
      String[] names
   )
```

getFTPSupportRfc2428ByLocation(location, names) throws ObjectDoesNotExist

Get whether backend IPv4 nodes understand the FTP EPRT and EPSV commands. This is a location specific function, any action will operate on the specified location.

```
   Boolean[] getFTPSupportRfc2428ByLocation(
      String location
      String[] names
   )
```

getFailpool(names) throws ObjectDoesNotExist

Get the pool to use when all nodes in a pool fail, for each of the named pools.

```
   String[] getFailpool(
      String[] names
   )
```

getFailpoolByLocation(location, names) throws ObjectDoesNotExist

Get the pool to use when all nodes in a pool fail, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
   String[] getFailpoolByLocation(
      String location
      String[] names
   )
```

getKeepalive(names) throws ObjectDoesNotExist

Get whether each of the named pools should maintain HTTP keepalive connections to the nodes.

```
   Boolean[] getKeepalive(
      String[] names
   )
```

getKeepaliveByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should maintain HTTP keepalive connections to the nodes. This is a location specific function, any action will operate on the specified location.

```
   Boolean[] getKeepaliveByLocation(
      String location
      String[] names
```

```
)
```

getKeepaliveNonIdempotent(names) throws ObjectDoesNotExist

Get whether each of the named pools should maintain HTTP keepalive connections to the nodes for non-idempotent requests.

```
Boolean[] getKeepaliveNonIdempotent(
   String[] names
)
```

getKeepaliveNonIdempotentByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should maintain HTTP keepalive connections to the nodes for non-idempotent requests. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getKeepaliveNonIdempotentByLocation(
   String location
   String[] names
)
```

getLoadBalancingAlgorithm(names) throws ObjectDoesNotExist

Get the load balancing algorithms that each of the named pools uses.

```
Pool.LoadBalancingAlgorithm[] getLoadBalancingAlgorithm(
   String[] names
)
```

getLoadBalancingAlgorithmByLocation(location, names) throws ObjectDoesNotExist

Get the load balancing algorithms that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
Pool.LoadBalancingAlgorithm[] getLoadBalancingAlgorithmByLocation(
   String location
   String[] names
)
```

getMaxConnectTime(names) throws ObjectDoesNotExist

Get the times that each of the named pools should wait for a connection to establish to a node before trying another node, in seconds.

```
Unsigned Integer[] getMaxConnectTime(
```

```
        String[] names
    )
```

getMaxConnectTimeByLocation(location, names) throws ObjectDoesNotExist

Get the times that each of the named pools should wait for a connection to establish to a node before trying another node, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxConnectTimeByLocation(
    String location
    String[] names
)
```

getMaxConnectionsPernode(names) throws ObjectDoesNotExist

Get is the maximum number of conncurrent connections allowed to each node in the pool per machine.

```
Unsigned Integer[] getMaxConnectionsPernode(
    String[] names
)
```

getMaxConnectionsPernodeByLocation(location, names) throws ObjectDoesNotExist

Get is the maximum number of conncurrent connections allowed to each node in the pool per machine. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxConnectionsPernodeByLocation(
    String location
    String[] names
)
```

getMaxIdleConnectionsPerNode(names) throws ObjectDoesNotExist

Get the maximum numbers of unused HTTP keepalive connections that each of the named pools should maintain to an individual node.

```
Unsigned Integer[] getMaxIdleConnectionsPerNode(
    String[] names
)
```

getMaxIdleConnectionsPerNodeByLocation(location, names) throws ObjectDoesNotExist

Get the maximum numbers of unused HTTP keepalive connections that each of the named pools should maintain to an individual node. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxIdleConnectionsPerNodeByLocation(
    String location
    String[] names
)
```

getMaxKeepalivesPerNode(names) throws ObjectDoesNotExist

getMaxKeepalivesPerNode is deprecated, please use getMaxIdleConnectionsPerNode instead.

```
Unsigned Integer[] getMaxKeepalivesPerNode(
    String[] names
)
```

getMaxKeepalivesPerNodeByLocation(location, names) throws ObjectDoesNotExist

getMaxKeepalivesPerNode is deprecated, please use getMaxIdleConnectionsPerNode instead. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxKeepalivesPerNodeByLocation(
    String location
    String[] names
)
```

getMaxQueueSize(names) throws ObjectDoesNotExist

Get is the maximum number of connections that can be queued due to connection limits.

```
Unsigned Integer[] getMaxQueueSize(
    String[] names
)
```

getMaxQueueSizeByLocation(location, names) throws ObjectDoesNotExist

Get is the maximum number of connections that can be queued due to connection limits. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxQueueSizeByLocation(
    String location
    String[] names
```

)

getMaxReplyTime(names) throws ObjectDoesNotExist

Get the time that each of the named pools should wait for a response from a node before either discarding the request or trying another node, in seconds (retryable requests only).

```
Unsigned Integer[] getMaxReplyTime(
   String[] names
)
```

getMaxReplyTimeByLocation(location, names) throws ObjectDoesNotExist

Get the time that each of the named pools should wait for a response from a node before either discarding the request or trying another node, in seconds (retryable requests only). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxReplyTimeByLocation(
   String location
   String[] names
)
```

getMonitors(names) throws ObjectDoesNotExist

Get the list of all monitors.

```
String[][] getMonitors(
   String[] names
)
```

getMonitorsByLocation(location, names) throws ObjectDoesNotExist

Get the list of all monitors. This is a location specific function, any action will operate on the specified location.

```
String[][] getMonitorsByLocation(
   String location
   String[] names
)
```

getNodeConnClose(names) throws ObjectDoesNotExist

Get whether all connections that have been sent to a node are closed when that node is marked as dead.

```
Boolean[] getNodeConnClose(
   String[] names
)
```

getNodeConnCloseByLocation(location, names) throws ObjectDoesNotExist

Get whether all connections that have been sent to a node are closed when that node is marked as dead. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getNodeConnCloseByLocation(
   String location
   String[] names
)
```

getNodeConnectionAttempts(names) throws ObjectDoesNotExist

Get the number of times your traffic manager should try and connect to a node before registering it as failed when passive monitoring is enabled.

```
Unsigned Integer[] getNodeConnectionAttempts(
   String[] names
)
```

getNodeConnectionAttemptsByLocation(location, names) throws ObjectDoesNotExist

Get the number of times your traffic manager should try and connect to a node before registering it as failed when passive monitoring is enabled. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getNodeConnectionAttemptsByLocation(
   String location
   String[] names
)
```

getNodeFailTime(names) throws ObjectDoesNotExist

Get the length of time a failed node should be isolated for before testing it with new traffic, in seconds

```
Unsigned Integer[] getNodeFailTime(
   String[] names
)
```

getNodeFailTimeByLocation(location, names) throws ObjectDoesNotExist

Get the length of time a failed node should be isolated for before testing it with new traffic, in seconds This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getNodeFailTimeByLocation(
   String location
```

```
      String[] names
   )
```

getNodeUseNagle(names) throws ObjectDoesNotExist

Get whether Nagle's algorithm should be used for TCP connections to the back-end nodes.

```
   Boolean[] getNodeUseNagle(
      String[] names
   )
```

getNodeUseNagleByLocation(location, names) throws ObjectDoesNotExist

Get whether Nagle's algorithm should be used for TCP connections to the back-end nodes. This is a location specific function, any action will operate on the specified location.

```
   Boolean[] getNodeUseNagleByLocation(
      String location
      String[] names
   )
```

getNodes(names) throws ObjectDoesNotExist

Get the lists of nodes for each of the named pools.

```
   String[][] getNodes(
      String[] names
   )
```

getNodesByLocation(location, names) throws ObjectDoesNotExist

Get the lists of nodes for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
   String[][] getNodesByLocation(
      String location
      String[] names
   )
```

getNodesConnectionCounts(nodes)

Get the number of active connections to each of the specified nodes.

```
   Integer[] getNodesConnectionCounts(
      String[] nodes
   )
```

getNodesLastUsed(nodes)

Get the number of seconds since each of the specified nodes was last used.

```
Integer[] getNodesLastUsed(
   String[] nodes
)
```

getNodesPriorityValue(names, nodes) throws ObjectDoesNotExist

For each of the named pools, get the priority values for the named nodes in each pool.

```
Pool.PriorityValueDefinition[][] getNodesPriorityValue(
   String[] names
   String[][] nodes
)
```

getNodesPriorityValueByLocation(location, names, nodes) throws ObjectDoesNotExist

For each of the named pools, get the priority values for the named nodes in each pool. This is a location specific function, any action will operate on the specified location.

```
Pool.PriorityValueDefinition[][] getNodesPriorityValueByLocation(
   String location
   String[] names
   String[][] nodes
)
```

getNodesWeightings(names, nodes) throws ObjectDoesNotExist

For each of the named pools, get the weighting values for the specified nodes in this pool.

```
Pool.WeightingsDefinition[][] getNodesWeightings(
   String[] names
   String[][] nodes
)
```

getNodesWeightingsByLocation(location, names, nodes) throws ObjectDoesNotExist

For each of the named pools, get the weighting values for the specified nodes in this pool. This is a location specific function, any action will operate on the specified location.

```
Pool.WeightingsDefinition[][] getNodesWeightingsByLocation(
   String location
   String[] names
   String[][] nodes
)
```

getNote(names) throws ObjectDoesNotExist

Get the note for each of the named pools.

```
String[] getNote(
   String[] names
)
```

getPassiveMonitoring(names) throws ObjectDoesNotExist

Get whether this pool uses passive monitoring.

```
Boolean[] getPassiveMonitoring(
   String[] names
)
```

getPassiveMonitoringByLocation(location, names) throws ObjectDoesNotExist

Get whether this pool uses passive monitoring. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getPassiveMonitoringByLocation(
   String location
   String[] names
)
```

getPersistence(names) throws ObjectDoesNotExist

Get the default Session Persistence classes that each of the named pools uses.

```
String[] getPersistence(
   String[] names
)
```

getPersistenceByLocation(location, names) throws ObjectDoesNotExist

Get the default Session Persistence classes that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
String[] getPersistenceByLocation(
   String location
   String[] names
)
```

getPoolNames()

Get the names of all of the configured pools.

```
String[] getPoolNames()
```

getPriorityEnabled(names) throws ObjectDoesNotExist

Get whether each of the named pools uses priority lists.

```
Boolean[] getPriorityEnabled(
    String[] names
)
```

getPriorityEnabledByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools uses priority lists. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getPriorityEnabledByLocation(
    String location
    String[] names
)
```

getPriorityNodes(names) throws ObjectDoesNotExist

Get the minimum number of highest-priority active nodes, for each of the named pools.

```
Unsigned Integer[] getPriorityNodes(
    String[] names
)
```

getPriorityNodesByLocation(location, names) throws ObjectDoesNotExist

Get the minimum number of highest-priority active nodes, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getPriorityNodesByLocation(
    String location
    String[] names
)
```

getPriorityValues(names) throws ObjectDoesNotExist

For each of the named pools, get the priority values for each of the nodes in each pool.

```
Pool.PriorityValueDefinition[][] getPriorityValues(
    String[] names
)
```

getPriorityValuesByLocation(location, names) throws ObjectDoesNotExist

For each of the named pools, get the priority values for each of the nodes in each pool. This is a location specific function, any action will operate on the specified location.

```
Pool.PriorityValueDefinition[][] getPriorityValuesByLocation(
   String location
   String[] names
)
```

getQueueTimeout(names) throws ObjectDoesNotExist

Get is the maximum time to keep a connections queued in seconds. A value of 0 will not timeout queued connections.

```
Unsigned Integer[] getQueueTimeout(
   String[] names
)
```

getQueueTimeoutByLocation(location, names) throws ObjectDoesNotExist

Get is the maximum time to keep a connections queued in seconds. A value of 0 will not timeout queued connections. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getQueueTimeoutByLocation(
   String location
   String[] names
)
```

getSMTPSendStartTLS(names) throws ObjectDoesNotExist

Get whether each of the named pools should upgrade SMTP connections to SSL using STARTTLS (the alternative is to encrypt the entire connection).

```
Boolean[] getSMTPSendStartTLS(
   String[] names
)
```

getSMTPSendStartTLSByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should upgrade SMTP connections to SSL using STARTTLS (the alternative is to encrypt the entire connection). This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSMTPSendStartTLSByLocation(
   String location
   String[] names
```

```
)
```

getSSLClientAuth(names) throws ObjectDoesNotExist

Get whether each of the named pools should use client authentication. If client authentication is enabled and a back-end node asks for a client authentication, a suitable certificate and private key will be used from the SSL Client Certificates catalog.

```
Boolean[] getSSLClientAuth(
   String[] names
)
```

getSSLClientAuthByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should use client authentication. If client authentication is enabled and a back-end node asks for a client authentication, a suitable certificate and private key will be used from the SSL Client Certificates catalog. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLClientAuthByLocation(
   String location
   String[] names
)
```

getSSLEncrypt(names) throws ObjectDoesNotExist

Get whether each of the named pools should encrypt data to the back-end nodes using SSL.

```
Boolean[] getSSLEncrypt(
   String[] names
)
```

getSSLEncryptByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should encrypt data to the back-end nodes using SSL. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLEncryptByLocation(
   String location
   String[] names
)
```

getSSLEnhance(names) throws ObjectDoesNotExist

Get whether each of the named pools should use SSL protocol enhancements. These enhancements allow Zeus Web Servers to run multiple SSL sites, and to discover the

client's IP address. Only use enable this if, for this pool, you are using Zeus Web Servers or Zeus Traffic Managers whose virtual servers have the 'ssl_trust_magic' setting enabled.

```
Boolean[] getSSLEnhance(
   String[] names
)
```

getSSLEnhanceByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should use SSL protocol enhancements. These enhancements allow Zeus Web Servers to run multiple SSL sites, and to discover the client's IP address. Only use enable this if, for this pool, you are using Zeus Web Servers or Zeus Traffic Managers whose virtual servers have the 'ssl_trust_magic' setting enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLEnhanceByLocation(
   String location
   String[] names
)
```

getSSLSendCloseAlerts(names) throws ObjectDoesNotExist

Get whether each of the named pools should send a close alert when they initiate socket disconnections.

```
Boolean[] getSSLSendCloseAlerts(
   String[] names
)
```

getSSLSendCloseAlertsByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should send a close alert when they initiate socket disconnections. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLSendCloseAlertsByLocation(
   String location
   String[] names
)
```

getSSLServerNameExtension(names) throws ObjectDoesNotExist

Get if we should send the server_name extension to the back-end node. This setting forces the use of at least TLS 1.0.

```
Boolean[] getSSLServerNameExtension(
   String[] names
)
```

getSSLServerNameExtensionByLocation(location, names) throws ObjectDoesNotExist

Get if we should send the server_name extension to the back-end node. This setting forces the use of at least TLS 1.0. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLServerNameExtensionByLocation(
   String location
   String[] names
)
```

getSSLStrictVerify(names) throws ObjectDoesNotExist

Get whether each of the named pools should perform strict certificate validation on SSL certificates from the back-end nodes.

```
Boolean[] getSSLStrictVerify(
   String[] names
)
```

getSSLStrictVerifyByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should perform strict certificate validation on SSL certificates from the back-end nodes. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getSSLStrictVerifyByLocation(
   String location
   String[] names
)
```

getTransparent(names) throws ObjectDoesNotExist

Get whether each of the named pools should make connections to the back-ends appear to originate from the source client IP address.

```
Boolean[] getTransparent(
   String[] names
)
```

getTransparentByLocation(location, names) throws ObjectDoesNotExist

Get whether each of the named pools should make connections to the back-ends appear to originate from the source client IP address. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getTransparentByLocation(
   String location
   String[] names
)
```

getUDPAcceptFrom(names) throws ObjectDoesNotExist

Get what sets of IP addresses and ports from which we should accept UDP responses.

```
Pool.UDPAcceptFrom[] getUDPAcceptFrom(
   String[] names
)
```

getUDPAcceptFromByLocation(location, names) throws ObjectDoesNotExist

Get what sets of IP addresses and ports from which we should accept UDP responses. This is a location specific function, any action will operate on the specified location.

```
Pool.UDPAcceptFrom[] getUDPAcceptFromByLocation(
   String location
   String[] names
)
```

getUDPAcceptFromIPMask(names) throws ObjectDoesNotExist

Get the mask to validate the IP of UDP responses with. Only used if UDPAcceptFromIP is set to 'ip_mask'.

```
String[] getUDPAcceptFromIPMask(
   String[] names
)
```

getUDPAcceptFromIPMaskByLocation(location, names) throws ObjectDoesNotExist

Get the mask to validate the IP of UDP responses with. Only used if UDPAcceptFromIP is set to 'ip_mask'. This is a location specific function, any action will operate on the specified location.

```
String[] getUDPAcceptFromIPMaskByLocation(
   String location
   String[] names
)
```

getWeightings(names) throws ObjectDoesNotExist

For each of the named pools, get the weightings for each of the nodes in each pool.

```
Pool.WeightingsDefinition[][] getWeightings(
```

```
   String[] names
)
```

getWeightingsByLocation(location, names) throws ObjectDoesNotExist

For each of the named pools, get the weightings for each of the nodes in each pool. This is a location specific function, any action will operate on the specified location.

```
Pool.WeightingsDefinition[][] getWeightingsByLocation(
   String location
   String[] names
)
```

removeDrainingNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove nodes from the lists of draining nodes, for each of the named pools.

```
void removeDrainingNodes(
   String[] names
   String[][] values
)
```

removeDrainingNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove nodes from the lists of draining nodes, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void removeDrainingNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

removeMonitors(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove monitors from each of the named pools.

```
void removeMonitors(
   String[] names
   String[][] values
)
```

removeMonitorsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove monitors from each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void removeMonitorsByLocation(
   String location
   String[] names
   String[][] values
)
```

removeNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove nodes from each of the named pools.

```
void removeNodes(
   String[] names
   String[][] values
)
```

removeNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Remove nodes from each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void removeNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

renamePool(names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename each of the named pools.

```
void renamePool(
   String[] names
   String[] new_names
)
```

setAutoscaleCloudcredentials(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the cloud credentials for this auto-scaled pool

```
void setAutoscaleCloudcredentials(
   String[] names
   String[] values
)
```

setAutoscaleCloudcredentialsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the cloud credentials for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleCloudcredentialsByLocation(
   String location
   String[] names
   String[] values
)
```

setAutoscaleEnabled(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether this pool uses auto-scaling.

```
void setAutoscaleEnabled(
   String[] names
   Boolean[] values
)
```

setAutoscaleEnabledByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether this pool uses auto-scaling. This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setAutoscaleExternal(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether autoscaling is handled externally or internally

```
void setAutoscaleExternal(
   String[] names
   Boolean[] values
)
```

setAutoscaleExternalByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether autoscaling is handled externally or internally This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleExternalByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setAutoscaleHysteresis(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the hysteresis period for an auto-scaled pool

```
void setAutoscaleHysteresis(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleHysteresisByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the hysteresis period for an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleHysteresisByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleImageid(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the image identifier

```
void setAutoscaleImageid(
   String[] names
   String[] values
)
```

setAutoscaleImageidByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the image identifier This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleImageidByLocation(
   String location
   String[] names
   String[] values
)
```

setAutoscaleIpstouse(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether to use the public or private IPs

```
void setAutoscaleIpstouse(
   String[] names
   Pool.AutoscaleIpstouse[] values
)
```

setAutoscaleIpstouseByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether to use the public or private IPs This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleIpstouseByLocation(
   String location
   String[] names
   Pool.AutoscaleIpstouse[] values
)
```

setAutoscaleMaxNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum number of nodes in an auto-scaled pool

```
void setAutoscaleMaxNodes(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleMaxNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum number of nodes in an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleMaxNodesByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setAutoscaleMinNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the minimum number of nodes in an auto-scaled pool

```
void setAutoscaleMinNodes(
    String[] names
    Unsigned Integer[] values
)
```

setAutoscaleMinNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the minimum number of nodes in an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleMinNodesByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setAutoscaleName(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the node name prefix for this auto-scaled pool

```
void setAutoscaleName(
    String[] names
    String[] values
)
```

setAutoscaleNameByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the node name prefix for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleNameByLocation(
   String location
   String[] names
   String[] values
)
```

setAutoscalePort(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the port number for this auto-scaled pool

```
void setAutoscalePort(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscalePortByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the port number for this auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscalePortByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleRefractory(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the refractory period for an auto-scaled pool

```
void setAutoscaleRefractory(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleRefractoryByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the refractory period for an auto-scaled pool This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleRefractoryByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleResponseTime(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the expected node response time in milliseconds

```
void setAutoscaleResponseTime(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleResponseTimeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the expected node response time in milliseconds This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleResponseTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleScaledownLevel(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the threshold of conforming requests for scaling down

```
void setAutoscaleScaledownLevel(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleScaledownLevelByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the threshold of conforming requests for scaling down This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleScaledownLevelByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleScaleupLevel(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the acceptable lower percentage of conforming requests

```
void setAutoscaleScaleupLevel(
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleScaleupLevelByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the acceptable lower percentage of conforming requests This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleScaleupLevelByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setAutoscaleSizeid(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the size identifier

```
void setAutoscaleSizeid(
   String[] names
   String[] values
)
```

setAutoscaleSizeidByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the size identifier This is a location specific function, any action will operate on the specified location.

```
void setAutoscaleSizeidByLocation(
   String location
   String[] names
   String[] values
)
```

setBandwidthClass(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the Bandwidth Classes that each of the named pools uses.

```
void setBandwidthClass(
   String[] names
   String[] values
)
```

setBandwidthClassByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the Bandwidth Classes that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
void setBandwidthClassByLocation(
   String location
   String[] names
   String[] values
)
```

setDisabledNodes(names, nodes) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the specified nodes to be disabled in the pool (all other nodes will remain in their existing state).

```
void setDisabledNodes(
   String[] names
   String[][] nodes
)
```

setDisabledNodesByLocation(location, names, nodes) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the specified nodes to be disabled in the pool (all other nodes will remain in their existing state). This is a location specific function, any action will operate on the specified location.

```
void setDisabledNodesByLocation(
   String location
   String[] names
   String[][] nodes
)
```

setDrainingNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the lists of draining nodes for each of the named pools.

```
void setDrainingNodes(
   String[] names
   String[][] values
)
```

setDrainingNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the lists of draining nodes for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void setDrainingNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

setErrorFile(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

This method is now obsolete and is replaced by VirtualServer.setErrorFile.

```
void setErrorFile(
   String[] names
   String[] values
)
```

setFTPSupportRfc2428(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether backend IPv4 nodes understand the FTP EPRT and EPSV commands.

```
void setFTPSupportRfc2428(
   String[] names
   Boolean[] values
)
```

setFTPSupportRfc2428ByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether backend IPv4 nodes understand the FTP EPRT and EPSV commands. This is a location specific function, any action will operate on the specified location.

```
void setFTPSupportRfc2428ByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setFailpool(names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Set the pool to use when all nodes in a pool fail, for each of the named pools.

```
void setFailpool(
   String[] names
   String[] values
)
```

setFailpoolByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Set the pool to use when all nodes in a pool fail, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void setFailpoolByLocation(
   String location
   String[] names
   String[] values
)
```

setKeepalive(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should maintain HTTP keepalive connections to the nodes.

```
void setKeepalive(
   String[] names
   Boolean[] values
)
```

setKeepaliveByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should maintain HTTP keepalive connections to the nodes. This is a location specific function, any action will operate on the specified location.

```
void setKeepaliveByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setKeepaliveNonIdempotent(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should maintain HTTP keepalive connections to the nodes for non-idempotent requests.

```
void setKeepaliveNonIdempotent(
   String[] names
   Boolean[] values
)
```

setKeepaliveNonIdempotentByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should maintain HTTP keepalive connections to the nodes for non-idempotent requests. This is a location specific function, any action will operate on the specified location.

```
void setKeepaliveNonIdempotentByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setLoadBalancingAlgorithm(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the load balancing algorithms that each of the named pools uses.

```
void setLoadBalancingAlgorithm(
   String[] names
   Pool.LoadBalancingAlgorithm[] values
)
```

setLoadBalancingAlgorithmByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the load balancing algorithms that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
void setLoadBalancingAlgorithmByLocation(
   String location
   String[] names
   Pool.LoadBalancingAlgorithm[] values
)
```

setMaxConnectTime(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the times that each of the named pools should wait for a connection to establish to a node before trying another node, in seconds.

```
void setMaxConnectTime(
   String[] names
   Unsigned Integer[] values
)
```

setMaxConnectTimeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the times that each of the named pools should wait for a connection to establish to a node before trying another node, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setMaxConnectTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxConnectionsPernode(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum number of conncurrent connections allowed to each node in the pool per machine.

```
void setMaxConnectionsPernode(
   String[] names
   Unsigned Integer[] values
)
```

setMaxConnectionsPernodeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum number of conncurrent connections allowed to each node in the pool per machine. This is a location specific function, any action will operate on the specified location.

```
void setMaxConnectionsPernodeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxIdleConnectionsPerNode(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum numbers of unused HTTP keepalive connections that each of the named pools should maintain to an individual node.

```
void setMaxIdleConnectionsPerNode(
   String[] names
   Unsigned Integer[] values
)
```

setMaxIdleConnectionsPerNodeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum numbers of unused HTTP keepalive connections that each of the named pools should maintain to an individual node. This is a location specific function, any action will operate on the specified location.

```
void setMaxIdleConnectionsPerNodeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxKeepalivesPerNode(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

setMaxKeepalivesPerNode is deprecated, please use setMaxIdleConnectionsPerNode instead.

```
void setMaxKeepalivesPerNode(
   String[] names
   Unsigned Integer[] values
)
```

setMaxKeepalivesPerNodeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

setMaxKeepalivesPerNode is deprecated, please use setMaxIdleConnectionsPerNode instead. This is a location specific function, any action will operate on the specified location.

```
void setMaxKeepalivesPerNodeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxQueueSize(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum number of connections that can be queued due to connection limits.

```
void setMaxQueueSize(
   String[] names
   Unsigned Integer[] values
)
```

setMaxQueueSizeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum number of connections that can be queued due to connection limits. This is a location specific function, any action will operate on the specified location.

```
void setMaxQueueSizeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMaxReplyTime(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the time that each of the named pools should wait for a response from a node before either discarding the request or trying another node, in seconds (retryable requests only).

```
void setMaxReplyTime(
   String[] names
   Unsigned Integer[] values
)
```

setMaxReplyTimeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the time that each of the named pools should wait for a response from a node before either discarding the request or trying another node, in seconds (retryable requests only). This is a location specific function, any action will operate on the specified location.

```
void setMaxReplyTimeByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setMonitors(names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Set the list of all monitors.

```
void setMonitors(
   String[] names
   String[][] values
)
```

setMonitorsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, InvalidOperation, DeploymentError

Set the list of all monitors. This is a location specific function, any action will operate on the specified location.

```
void setMonitorsByLocation(
   String location
   String[] names
   String[][] values
)
```

setNodeConnClose(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether all connections that have been sent to a node are closed when that node is marked as dead.

```
void setNodeConnClose(
   String[] names
   Boolean[] values
)
```

setNodeConnCloseByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether all connections that have been sent to a node are closed when that node is marked as dead. This is a location specific function, any action will operate on the specified location.

```
void setNodeConnCloseByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setNodeConnectionAttempts(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the number of times your traffic manager should try and connect to a node before registering it as failed when passive monitoring is enabled.

```
void setNodeConnectionAttempts(
   String[] names
   Unsigned Integer[] values
)
```

setNodeConnectionAttemptsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the number of times your traffic manager should try and connect to a node before registering it as failed when passive monitoring is enabled. This is a location specific function, any action will operate on the specified location.

```
void setNodeConnectionAttemptsByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setNodeFailTime(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the length of time a failed node should be isolated for before testing it with new traffic, in seconds

```
void setNodeFailTime(
    String[] names
    Unsigned Integer[] values
)
```

setNodeFailTimeByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the length of time a failed node should be isolated for before testing it with new traffic, in seconds This is a location specific function, any action will operate on the specified location.

```
void setNodeFailTimeByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setNodeUseNagle(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether Nagle's algorithm should be used for TCP connections to the back-end nodes.

```
void setNodeUseNagle(
    String[] names
    Boolean[] values
)
```

setNodeUseNagleByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether Nagle's algorithm should be used for TCP connections to the back-end nodes. This is a location specific function, any action will operate on the specified location.

```
void setNodeUseNagleByLocation(
    String location
    String[] names
    Boolean[] values
)
```

setNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the lists of nodes for each of the named pools.

```
void setNodes(
   String[] names
   String[][] values
)
```

setNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the lists of nodes for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void setNodesByLocation(
   String location
   String[] names
   String[][] values
)
```

setNodesPriorityValue(names, node_values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the priority values for the named nodes in each pool.

```
void setNodesPriorityValue(
   String[] names
   Pool.PriorityValueDefinition[][] node_values
)
```

setNodesPriorityValueByLocation(location, names, node_values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the priority values for the named nodes in each pool. This is a location specific function, any action will operate on the specified location.

```
void setNodesPriorityValueByLocation(
   String location
   String[] names
   Pool.PriorityValueDefinition[][] node_values
)
```

setNodesWeightings(names, nodes_values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the weighting (for the Weighted Round Robin algorithm) for each node in that pool.

```
void setNodesWeightings(
    String[] names
    Pool.WeightingsDefinition[][] nodes_values
)
```

setNodesWeightingsByLocation(location, names, nodes_values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

For each of the named pools, set the weighting (for the Weighted Round Robin algorithm) for each node in that pool. This is a location specific function, any action will operate on the specified location.

```
void setNodesWeightingsByLocation(
    String location
    String[] names
    Pool.WeightingsDefinition[][] nodes_values
)
```

setNote(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the note for each of the named pools.

```
void setNote(
    String[] names
    String[] values
)
```

setPassiveMonitoring(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether this pool uses passive monitoring.

```
void setPassiveMonitoring(
    String[] names
    Boolean[] values
)
```

setPassiveMonitoringByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether this pool uses passive monitoring. This is a location specific function, any action will operate on the specified location.

```
void setPassiveMonitoringByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setPersistence(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the default Session Persistence classes that each of the named pools uses.

```
void setPersistence(
   String[] names
   String[] values
)
```

setPersistenceByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the default Session Persistence classes that each of the named pools uses. This is a location specific function, any action will operate on the specified location.

```
void setPersistenceByLocation(
   String location
   String[] names
   String[] values
)
```

setPriorityEnabled(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools uses priority lists.

```
void setPriorityEnabled(
   String[] names
   Boolean[] values
)
```

setPriorityEnabledByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools uses priority lists. This is a location specific function, any action will operate on the specified location.

```
void setPriorityEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setPriorityNodes(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the minimum number of highest-priority active nodes, for each of the named pools.

```
void setPriorityNodes(
   String[] names
   Unsigned Integer[] values
)
```

setPriorityNodesByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the minimum number of highest-priority active nodes, for each of the named pools. This is a location specific function, any action will operate on the specified location.

```
void setPriorityNodesByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setQueueTimeout(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum time to keep a connections queued in seconds. A value of 0 will not timeout queued connections.

```
void setQueueTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setQueueTimeoutByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set is the maximum time to keep a connections queued in seconds. A value of 0 will not timeout queued connections. This is a location specific function, any action will operate on the specified location.

```
void setQueueTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setSMTPSendStartTLS(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should upgrade SMTP connections to SSL using STARTTLS (the alternative is to encrypt the entire connection).

```
void setSMTPSendStartTLS(
   String[] names
   Boolean[] values
)
```

setSMTPSendStartTLSByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should upgrade SMTP connections to SSL using STARTTLS (the alternative is to encrypt the entire connection). This is a location specific function, any action will operate on the specified location.

```
void setSMTPSendStartTLSByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLClientAuth(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should use client authentication. If client authentication is enabled and a back-end node asks for a client authentication, a suitable certificate and private key will be used from the SSL Client Certificates catalog.

```
void setSSLClientAuth(
   String[] names
   Boolean[] values
)
```

setSSLClientAuthByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should use client authentication. If client authentication is enabled and a back-end node asks for a client authentication, a suitable certificate and private key will be used from the SSL Client Certificates catalog. This is a location specific function, any action will operate on the specified location.

```
void setSSLClientAuthByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLEncrypt(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should encrypt data to the back-end nodes using SSL.

```
void setSSLEncrypt(
   String[] names
   Boolean[] values
)
```

setSSLEncryptByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should encrypt data to the back-end nodes using SSL. This is a location specific function, any action will operate on the specified location.

```
void setSSLEncryptByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLEnhance(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should use SSL protocol enhancements. These enhancements allow Zeus Web Servers to run multiple SSL sites, and to discover the client's IP address. Only use enable this if, for this pool, you are using Zeus Web Servers or Zeus Traffic Managers whose virtual servers have the 'ssl_trust_magic' setting enabled.

```
void setSSLEnhance(
   String[] names
   Boolean[] values
)
```

setSSLEnhanceByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should use SSL protocol enhancements. These enhancements allow Zeus Web Servers to run multiple SSL sites, and to discover the client's IP address. Only use enable this if, for this pool, you are using Zeus Web Servers or Zeus Traffic Managers whose virtual servers have the 'ssl_trust_magic' setting enabled. This is a location specific function, any action will operate on the specified location.

```
void setSSLEnhanceByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLSendCloseAlerts(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should send a close alert when they initiate socket disconnections.

```
void setSSLSendCloseAlerts(
   String[] names
   Boolean[] values
)
```

setSSLSendCloseAlertsByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should send a close alert when they initiate socket disconnections. This is a location specific function, any action will operate on the specified location.

```
void setSSLSendCloseAlertsByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLServerNameExtension(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set if we should send the server_name extension to the back-end node. This setting forces the use of at least TLS 1.0.

```
void setSSLServerNameExtension(
   String[] names
```

```
   Boolean[] values
)
```

setSSLServerNameExtensionByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set if we should send the server_name extension to the back-end node. This setting forces the use of at least TLS 1.0. This is a location specific function, any action will operate on the specified location.

```
void setSSLServerNameExtensionByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setSSLStrictVerify(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should perform strict certificate validation on SSL certificates from the back-end nodes.

```
void setSSLStrictVerify(
   String[] names
   Boolean[] values
)
```

setSSLStrictVerifyByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should perform strict certificate validation on SSL certificates from the back-end nodes. This is a location specific function, any action will operate on the specified location.

```
void setSSLStrictVerifyByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setTransparent(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should make connections to the back-ends appear to originate from the source client IP address.

```
void setTransparent(
   String[] names
```

```
      Boolean[] values
   )
```

setTransparentByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether each of the named pools should make connections to the back-ends appear to originate from the source client IP address. This is a location specific function, any action will operate on the specified location.

```
   void setTransparentByLocation(
      String location
      String[] names
      Boolean[] values
   )
```

setUDPAcceptFrom(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set what sets of IP addresses and ports from which we should accept UDP responses.

```
   void setUDPAcceptFrom(
      String[] names
      Pool.UDPAcceptFrom[] values
   )
```

setUDPAcceptFromByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set what sets of IP addresses and ports from which we should accept UDP responses. This is a location specific function, any action will operate on the specified location.

```
   void setUDPAcceptFromByLocation(
      String location
      String[] names
      Pool.UDPAcceptFrom[] values
   )
```

setUDPAcceptFromIPMask(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the mask to validate the IP of UDP responses with. Only used if UDPAcceptFromIP is set to 'ip_mask'.

```
   void setUDPAcceptFromIPMask(
      String[] names
      String[] values
   )
```

setUDPAcceptFromIPMaskByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the mask to validate the IP of UDP responses with. Only used if UDPAcceptFromIP is set to 'ip_mask'. This is a location specific function, any action will operate on the specified location.

```
void setUDPAcceptFromIPMaskByLocation(
   String location
   String[] names
   String[] values
)
```

6.3.2 Structures

Pool.PriorityValueDefinition

This structure contains the priority for a particular node. The priority is used when using the priority lists functionality.

```
struct Pool.PriorityValueDefinition {
   # The name of the node.
   String node;

   # The priority value.
   Integer priority;
}
```

Pool.WeightingsDefinition

This structure contains the weighting for a particular node. The weighting is used when using the Weighted Round Robin algorithm functionality.

```
struct Pool.WeightingsDefinition {
   # The name of the node.
   String node;

   # The weighting value.
   Integer weighting;
}
```

6.3.3 Enumerations

Pool.AutoscaleIpstouse

```
enum Pool.AutoscaleIpstouse {
   # Public IP addresses
```

```
    publicips,

    # Private IP addresses
    privateips
}
```

Pool.LoadBalancingAlgorithm

```
enum Pool.LoadBalancingAlgorithm {
    # Round Robin
    roundrobin,

    # Weighted Round Robin
    wroundrobin,

    # Perceptive
    cells,

    # Least Connections
    connections,

    # Weighted Least Connections
    wconnections,

    # Fastest Response Time
    responsetimes,

    # Random node
    random
}
```

Pool.UDPAcceptFrom

```
enum Pool.UDPAcceptFrom {
    # Only the IP address and port to which the request was sent
    dest_only,

    # Only the IP address to which the request was sent, but from
    # any port
    dest_ip_only,

    # Only a specific set of IP addresses, but from any port
    ip_mask,

    # Any IP address and any port
    all
}
```

6.4 TrafficIPGroups

URI: `http://soap.zeus.com/zxtm/1.0/TrafficIPGroups/`

The TrafficIPGroup interface allows management of Traffic IP Group objects. Using this interface, you can create, delete and rename Traffic IP Group objects, and manage their configuration.

6.4.1 Methods

addIPAddresses(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Add new IP addresses to each of the named traffic IP groups.

```
void addIPAddresses(
   String[] names
   String[][] values
)
```

addPassiveMachine(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Add machines to the lists of passive machines, for each of the named traffic IP groups.

```
void addPassiveMachine(
   String[] names
   String[][] values
)
```

addTrafficIPGroup(names, details) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidInput, InvalidOperation

Add the new named Traffic IP Groups, using the provided details.

```
void addTrafficIPGroup(
   String[] names
   TrafficIPGroups.Details[] details
)
```

addTrafficManager(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new traffic managers to each of the named traffic IP groups.

```
void addTrafficManager(
   String[] names
   String[][] values
)
```

deleteSpecificSubnetMappings(mappings) throws InvalidInput

Delete specified interface network mappings.

```
void deleteSpecificSubnetMappings(
   TrafficIPGroups.SubnetMappingPerHost[] mappings
)
```

deleteSubnetMappings()

Delete all interface network mappings.

```
void deleteSubnetMappings()
```

deleteTrafficIPGroup(names) throws ObjectDoesNotExist, ObjectInUse, DeploymentError, InvalidOperation

Delete the named Traffic IP Groups.

```
void deleteTrafficIPGroup(
   String[] names
)
```

getAvailableTrafficManagers()

Get the names of all of the Traffic Managers in the cluster.

```
String[] getAvailableTrafficManagers()
```

getEnabled(names) throws ObjectDoesNotExist

Get whether this traffic IP group is enabled or not.

```
Boolean[] getEnabled(
   String[] names
)
```

getIPAddresses(names) throws ObjectDoesNotExist

Get the IP addresses that are managed by each of the named traffic IP groups.

```
String[][] getIPAddresses(
   String[] names
)
```

getIPDistributionMode(names) throws ObjectDoesNotExist

Get how traffic IPs will be distributed across the machines in the cluster. If "multihosted" mode is used, the multicast IP must be set first.

```
TrafficIPGroups.IPDistributionMode[] getIPDistributionMode(
   String[] names
)
```

getKeepTogether(names) throws ObjectDoesNotExist

Get the KeepTogether attribute for each of the named traffic IP groups.

```
Boolean[] getKeepTogether(
   String[] names
)
```

getMulticastIP(names) throws ObjectDoesNotExist

Get the multicast IP group that is used to share data across machines in the cluster. This setting is only used if the traffic IP is using 'multihosted' distribution mode.

```
String[] getMulticastIP(
   String[] names
)
```

getNetworkInterfaces()

Get a list of network interfaces for all machines in the cluster.

```
TrafficIPGroups.NetworkInterface[] getNetworkInterfaces()
```

getNote(names) throws ObjectDoesNotExist

Get the note for each of the named traffic IP groups.

```
String[] getNote(
   String[] names
)
```

getPassiveMachine(names) throws ObjectDoesNotExist

Get the lists of passive machines in each of the named traffic IP groups.

```
String[][] getPassiveMachine(
   String[] names
)
```

getSubnetMappings(hostnames) throws InvalidInput

Get interface to CIDR subnet mappings.

```
TrafficIPGroups.SubnetMappingPerHost[] getSubnetMappings(
   String[] hostnames
)
```

getTrafficIPGroupNames()

Get the names of all of the configured Traffic IP Groups.

```
String[] getTrafficIPGroupNames()
```

getTrafficManager(names) throws ObjectDoesNotExist

Get the traffic managers that manage the IP addresses in each of the named traffic IP groups.

```
String[][] getTrafficManager(
   String[] names
)
```

getUseClientSourcePort(names) throws ObjectDoesNotExist

Get whether the source port is taken into account when deciding which traffic manager should handle the request. This setting is only used if the Traffic IP is using 'multihosted' distribution mode.

```
Boolean[] getUseClientSourcePort(
   String[] names
)
```

removeIPAddresses(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Remove the named IP addresses from each of the named traffic IP groups.

```
void removeIPAddresses(
   String[] names
   String[][] values
)
```

removePassiveMachine(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Remove the named machines from the list of passive machines, for each of the named traffic IP groups.

```
void removePassiveMachine(
   String[] names
   String[][] values
)
```

removeTrafficManager(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidOperation

Remove the named traffic managers from each named traffic IP group.

```
void removeTrafficManager(
   String[] names
   String[][] values
)
```

renameTrafficIPGroup(names, new_names) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Rename each of the named Traffic IP Groups.

```
void renameTrafficIPGroup(
   String[] names
   String[] new_names
)
```

setEnabled(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether this traffic IP group is enabled or not.

```
void setEnabled(
   String[] names
   Boolean[] values
)
```

setIPAddresses(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the IP addresses that are managed by each of the named traffic IP groups.

```
void setIPAddresses(
   String[] names
   String[][] values
)
```

setIPDistributionMode(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set how traffic IPs will be distributed across the machines in the cluster. If "multihosted" mode is used, the multicast IP must be set first.

```
void setIPDistributionMode(
    String[] names
    TrafficIPGroups.IPDistributionMode[] values
)
```

setKeepTogether(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the KeepTogether attribute for each of the named traffic IP groups.

```
void setKeepTogether(
    String[] names
    Boolean[] values
)
```

setMulticastIP(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the multicast IP group that is used to share data across machines in the cluster. This setting is only used if the traffic IP is using 'multihosted' distribution mode.

```
void setMulticastIP(
    String[] names
    String[] values
)
```

setNote(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the note for each of the named traffic IP groups.

```
void setNote(
    String[] names
    String[] values
)
```

setPassiveMachine(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the lists of passive machines in each of the named traffic IP groups.

```
void setPassiveMachine(
    String[] names
```

```
        String[][] values
    )
```

setSubnetMappings(mappings) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Update interface to CIDR subnet mappings.

```
void setSubnetMappings(
    TrafficIPGroups.SubnetMappingPerHost[] mappings
)
```

setTrafficManager(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the traffic managers that manage the IP addresses in each of the named traffic IP groups.

```
void setTrafficManager(
    String[] names
    String[][] values
)
```

setUseClientSourcePort(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set whether the source port is taken into account when deciding which traffic manager should handle the request. This setting is only used if the Traffic IP is using 'multihosted' distribution mode.

```
void setUseClientSourcePort(
    String[] names
    Boolean[] values
)
```

6.4.2 Structures

TrafficIPGroups.Details

This structure contains the basic details of a Traffic IP Group: the nodes, and the traffic managers that the Traffic IP group spans. It is used when creating a new Traffic IP Group.

```
struct TrafficIPGroups.Details {
    # The IP addresses in the Traffic IP Group.
    String[] ipaddresses;

    # The names of the traffic managers that will manage the IP
    # Addresses.
```

```
    String[] machines;
}
```

TrafficIPGroups.NetworkInterface

This structure displays the network interfaces of all machines in the cluster.

```
struct TrafficIPGroups.NetworkInterface {
    # The traffic manager in the cluster.
    String hostname;

    # The network interfaces configured in this traffic manager.
    String[] interfaces;
}
```

TrafficIPGroups.SubnetMapping

This structure contains mappings of network interface to CIDR subnets. These mappings are used to raise a TrafficIP on a desired interface.

```
struct TrafficIPGroups.SubnetMapping {
    # The interface on the system.
    String interface;

    # The subnets mappings for the interface.
    String[] subnets;
}
```

TrafficIPGroups.SubnetMappingPerHost

This structure shows the traffic IP subnet mapping per host machine in the cluster.

```
struct TrafficIPGroups.SubnetMappingPerHost {
    # The traffic manager in the cluster.
    String hostname;

    # The subnets mappings for this traffic manager.
    TrafficIPGroups.SubnetMapping[] subnetmappings;
}
```

6.4.3 Enumerations

TrafficIPGroups.IPDistributionMode

```
enum TrafficIPGroups.IPDistributionMode {
    # Raise each address on a single machine (Single-Hosted mode)
    singlehosted,

    # Raise each address on every machine in the group
```

```
        # (Multi-Hosted mode) - IPv4 only
        multihosted,

        # Use an EC2 Elastic IP address.
        ec2elastic
    }
```

6.5   Catalog.Rule

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/Rule/`

The Catalog.Rule interface allows management of TrafficScript Rules. Using this interface, you can create, delete and rename rules, and manage their configuration. You can also syntax-check rule fragments.

6.5.1   Methods

addRule(names, texts) throws InvalidObjectName, ObjectAlreadyExists, DeploymentError

Add new rules to the catalog.

```
void addRule(
    String[] names
    String[] texts
)
```

checkSyntax(rule_text)

Check the syntax of each of the supplied TrafficScript rule texts. This method does not modify any configuration.

```
Catalog.Rule.SyntaxCheck[] checkSyntax(
    String[] rule_text
)
```

copyRule(names, new_names) throws InvalidObjectName, ObjectAlreadyExists, ObjectDoesNotExist, DeploymentError

Copy the named rules in the catalog.

```
void copyRule(
    String[] names
    String[] new_names
)
```

deleteRule(names) throws ObjectInUse, ObjectDoesNotExist, DeploymentError, InvalidOperation

Delete the named rules from the catalog.

```
void deleteRule(
   String[] names
)
```

getRuleDetails(names) throws ObjectDoesNotExist, DeploymentError

Get the rule text and notes (if any), for each of the named rules.

```
Catalog.Rule.RuleInfo[] getRuleDetails(
   String[] names
)
```

getRuleNames()

Get the names of all rules in the catalog.

```
String[] getRuleNames()
```

renameRule(names, new_names) throws InvalidObjectName, ObjectAlreadyExists, ObjectDoesNotExist, DeploymentError, InvalidOperation

Rename the named rules in the catalog.

```
void renameRule(
   String[] names
   String[] new_names
)
```

setRuleNotes(names, notes) throws ObjectDoesNotExist, DeploymentError

Sets the descriptive notes for each of the named rules in the catalog.

```
void setRuleNotes(
   String[] names
   String[] notes
)
```

setRuleText(names, text) throws ObjectDoesNotExist, DeploymentError

Set the TrafficScript text for each of the named rules in the catalog.

```
void setRuleText(
   String[] names
   String[] text
```

```
    )
```

6.5.2 Structures

Catalog.Rule.RuleInfo

This structure contains basic information for a rule in the catalog.

```
struct Catalog.Rule.RuleInfo {
    # The rule text
    String rule_text;

    # The descriptive notes for the rule.
    String rule_notes;
}
```

Catalog.Rule.SyntaxCheck

This structure contains the results of a rule syntax check against a rule in the catalog.

```
struct Catalog.Rule.SyntaxCheck {
    # Whether the rule text is valid or not.
    Boolean valid;

    # Any warnings (such as deprecated functions) associated with
    # the rule text.
    String warnings;

    # Any errors (such as syntax errors) associated with the rule
    # text.
    String errors;
}
```

6.6 Catalog.Monitor

URI: http://soap.zeus.com/zxtm/1.0/Catalog/Monitor/

The Catalog.Monitor interface allows management of Custom Monitors. Using this interface, you can create, delete and rename custom monitors, and manage their configuration.

6.6.1 Methods

addMonitors(names) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError

Add new monitors (defaults to TCP transaction monitor, monitoring each node separately).

```
void addMonitors(
    String[] names
)
```

addProgramArguments(names, arguments) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Adds a set of arguments to the specified monitors. The monitors specified must be of type 'program'.

```
void addProgramArguments(
    String[] names
    Catalog.Monitor.Argument[][] arguments
)
```

copyMonitors(names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Copy the named monitors.

```
void copyMonitors(
    String[] names
    String[] new_names
)
```

deleteMonitorProgram(names) throws ObjectDoesNotExist, DeploymentError, ObjectInUse

Delete the named monitor programs.

```
void deleteMonitorProgram(
    String[] names
)
```

deleteMonitors(names) throws ObjectDoesNotExist, InvalidOperation, DeploymentError, ObjectInUse

Delete these monitors.

```
void deleteMonitors(
    String[] names
)
```

downloadMonitorProgram(name) throws ObjectDoesNotExist

Download the named monitor program.

```
Binary Data downloadMonitorProgram(
```

```
        String name
    )
```

getAllMonitorNames()

Get the names of all monitors.

```
    String[] getAllMonitorNames()
```

getAuthentication(names) throws ObjectDoesNotExist, InvalidOperation

Get the authentication (user:password) that each of the named monitors should use in the
test HTTP request.

```
    String[] getAuthentication(
        String[] names
    )
```

getAuthenticationByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the authentication (user:password) that each of the named monitors should use in the
test HTTP request. This is a location specific function, any action will operate on the
specified location.

```
    String[] getAuthenticationByLocation(
        String location
        String[] names
    )
```

getBackOff(names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should back-off after it has failed.

```
    Boolean[] getBackOff(
        String[] names
    )
```

getBackOffByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should back-off after it has failed. This is a
location specific function, any action will operate on the specified location.

```
    Boolean[] getBackOffByLocation(
        String location
        String[] names
    )
```

getBodyRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that that each of the named monitors' HTTP response must match.

```
String[] getBodyRegex(
   String[] names
)
```

getBodyRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that that each of the named monitors' HTTP response must match. This is a location specific function, any action will operate on the specified location.

```
String[] getBodyRegexByLocation(
   String location
   String[] names
)
```

getCloseString(names) throws ObjectDoesNotExist, InvalidOperation

Get an optional string that each of the named monitors should write to the server before closing the connection.

```
String[] getCloseString(
   String[] names
)
```

getCloseStringByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get an optional string that each of the named monitors should write to the server before closing the connection. This is a location specific function, any action will operate on the specified location.

```
String[] getCloseStringByLocation(
   String location
   String[] names
)
```

getCustomMonitorNames()

Get the names of all the custom monitors.

```
String[] getCustomMonitorNames()
```

getDelay(names) throws ObjectDoesNotExist, InvalidOperation

Get the minimum time between calls to each of the named monitors (in seconds).

```
Unsigned Integer[] getDelay(
   String[] names
)
```

getDelayByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the minimum time between calls to each of the named monitors (in seconds). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getDelayByLocation(
   String location
   String[] names
)
```

getFailures(names) throws ObjectDoesNotExist, InvalidOperation

Get the number of failures required, by each of the named monitors, before a node is classed as unavailable.

```
Unsigned Integer[] getFailures(
   String[] names
)
```

getFailuresByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the number of failures required, by each of the named monitors, before a node is classed as unavailable. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getFailuresByLocation(
   String location
   String[] names
)
```

getHealthOnly(names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should monitor health only (ignore load).

```
Boolean[] getHealthOnly(
   String[] names
)
```

getHealthOnlyByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should monitor health only (ignore load). This is a location specific function, any action will operate on the specified location.

```
Boolean[] getHealthOnlyByLocation(
   String location
   String[] names
)
```

getHostHeader(names) throws ObjectDoesNotExist, InvalidOperation

Get the host header that each of the named monitors should use in the test HTTP request.

```
String[] getHostHeader(
   String[] names
)
```

getHostHeaderByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the host header that each of the named monitors should use in the test HTTP request. This is a location specific function, any action will operate on the specified location.

```
String[] getHostHeaderByLocation(
   String location
   String[] names
)
```

getMachine(names) throws ObjectDoesNotExist, InvalidOperation

Get the machine that each of the named monitors should monitor (must be a valid hostname:port or a hostname for Ping monitors).

```
String[] getMachine(
   String[] names
)
```

getMachineByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the machine that each of the named monitors should monitor (must be a valid hostname:port or a hostname for Ping monitors). This is a location specific function, any action will operate on the specified location.

```
String[] getMachineByLocation(
```

```
        String location
        String[] names
    )
```

getMaxResponseLen(names) throws ObjectDoesNotExist, InvalidOperation

Get the maximum amount of data (in bytes) that each of the named monitors should read back from a server (0 = unlimited).

```
Unsigned Integer[] getMaxResponseLen(
    String[] names
)
```

getMaxResponseLenByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the maximum amount of data (in bytes) that each of the named monitors should read back from a server (0 = unlimited). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxResponseLenByLocation(
    String location
    String[] names
)
```

getMonitorProgramNames()

Get the names of all the uploaded monitor programs. These are the programs that can be executed by custom program monitors.

```
String[] getMonitorProgramNames()
```

getNote(names) throws ObjectDoesNotExist, InvalidOperation

Get the note for each of the named Monitors.

```
String[] getNote(
    String[] names
)
```

getPath(names) throws ObjectDoesNotExist, InvalidOperation

Get the path that each of the named monitors should use in the test HTTP request.

```
String[] getPath(
    String[] names
)
```

getPathByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the path that each of the named monitors should use in the test HTTP request. This is a location specific function, any action will operate on the specified location.

```
String[] getPathByLocation(
   String location
   String[] names
)
```

getProgram(names) throws ObjectDoesNotExist, InvalidOperation

Get the name of the program that each named monitor runs.

```
String[] getProgram(
   String[] names
)
```

getProgramArguments(names) throws ObjectDoesNotExist, InvalidOperation

Gets all arguments for the specified monitors. The monitors specified must be of type 'program'.

```
Catalog.Monitor.Argument[][] getProgramArguments(
   String[] names
)
```

getResponseRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the regular expression that each of the named monitors should match against the server response.

```
String[] getResponseRegex(
   String[] names
)
```

getResponseRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the regular expression that each of the named monitors should match against the server response. This is a location specific function, any action will operate on the specified location.

```
String[] getResponseRegexByLocation(
   String location
   String[] names
)
```

getRtspBodyRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that each of the named monitors' RTSP response must
match.

```
String[] getRtspBodyRegex(
   String[] names
)
```

getRtspBodyRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that each of the named monitors' RTSP response must
match. This is a location specific function, any action will operate on the specified location.

```
String[] getRtspBodyRegexByLocation(
   String location
   String[] names
)
```

getRtspPath(names) throws ObjectDoesNotExist, InvalidOperation

Get the path that each of the named monitors should use in the test RTSP request.

```
String[] getRtspPath(
   String[] names
)
```

getRtspPathByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the path that each of the named monitors should use in the test RTSP request. This is
a location specific function, any action will operate on the specified location.

```
String[] getRtspPathByLocation(
   String location
   String[] names
)
```

getRtspStatusRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that each of the named monitors' RTSP response
must match.

```
String[] getRtspStatusRegex(
   String[] names
)
```

getRtspStatusRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that each of the named monitors' RTSP response must match. This is a location specific function, any action will operate on the specified location.

```
String[] getRtspStatusRegexByLocation(
   String location
   String[] names
)
```

getScope(names) throws ObjectDoesNotExist, InvalidOperation

Get the scope of each named monitor.

```
Catalog.Monitor.Scope[] getScope(
   String[] names
)
```

getSipBodyRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that that each of the named monitors' SIP response must match.

```
String[] getSipBodyRegex(
   String[] names
)
```

getSipBodyRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the body regular expression that that each of the named monitors' SIP response must match. This is a location specific function, any action will operate on the specified location.

```
String[] getSipBodyRegexByLocation(
   String location
   String[] names
)
```

getSipStatusRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that that each of the named monitors' SIP response must match.

```
String[] getSipStatusRegex(
   String[] names
)
```

getSipStatusRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that that each of the named monitors' SIP response must match. This is a location specific function, any action will operate on the specified location.

```
String[] getSipStatusRegexByLocation(
    String location
    String[] names
)
```

getSipTransport(names) throws ObjectDoesNotExist, InvalidOperation

Get the transport protocol that the monitor will use

```
Catalog.Monitor.SipTransport[] getSipTransport(
    String[] names
)
```

getSipTransportByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the transport protocol that the monitor will use This is a location specific function, any action will operate on the specified location.

```
Catalog.Monitor.SipTransport[] getSipTransportByLocation(
    String location
    String[] names
)
```

getStatusRegex(names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that that each of the named monitors' HTTP response must match.

```
String[] getStatusRegex(
    String[] names
)
```

getStatusRegexByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the status code regular expression that that each of the named monitors' HTTP response must match. This is a location specific function, any action will operate on the specified location.

```
String[] getStatusRegexByLocation(
    String location
```

```
        String[] names
    )
```

getTimeout(names) throws ObjectDoesNotExist, InvalidOperation

Get the maximum time that an individual instance, of each of the named monitors, is allowed to run for (in seconds).

```
    Unsigned Integer[] getTimeout(
        String[] names
    )
```

getTimeoutByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the maximum time that an individual instance, of each of the named monitors, is allowed to run for (in seconds). This is a location specific function, any action will operate on the specified location.

```
    Unsigned Integer[] getTimeoutByLocation(
        String location
        String[] names
    )
```

getType(names) throws ObjectDoesNotExist, InvalidOperation

Get the internal monitor type to use for each named monitor.

```
    Catalog.Monitor.Type[] getType(
        String[] names
    )
```

getUDPAcceptAll(names) throws ObjectDoesNotExist, InvalidOperation

Get if the monitor should accept responses from any IP and port. UDP monitors only.

```
    Boolean[] getUDPAcceptAll(
        String[] names
    )
```

getUDPAcceptAllByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get if the monitor should accept responses from any IP and port. UDP monitors only. This is a location specific function, any action will operate on the specified location.

```
    Boolean[] getUDPAcceptAllByLocation(
        String location
```

```
   String[] names
)
```

getUseSSL(names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors can connect using SSL.

```
Boolean[] getUseSSL(
   String[] names
)
```

getUseSSLByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors can connect using SSL. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getUseSSLByLocation(
   String location
   String[] names
)
```

getVerbose(names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should emit verbose logging (useful for diagnostics).

```
Boolean[] getVerbose(
   String[] names
)
```

getVerboseByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get whether each of the named monitors should emit verbose logging (useful for diagnostics). This is a location specific function, any action will operate on the specified location.

```
Boolean[] getVerboseByLocation(
   String location
   String[] names
)
```

getWriteString(names) throws ObjectDoesNotExist, InvalidOperation

Get the string that each of the named monitors should write down the TCP connection.

```
String[] getWriteString(
```

```
      String[] names
   )
```

getWriteStringByLocation(location, names) throws ObjectDoesNotExist, InvalidOperation

Get the string that each of the named monitors should write down the TCP connection. This is a location specific function, any action will operate on the specified location.

```
   String[] getWriteStringByLocation(
      String location
      String[] names
   )
```

removeProgramArguments(names, arguments) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Removes a set of arguments from the specified monitors. The monitors specified must be of type 'program'.

```
   void removeProgramArguments(
      String[] names
      String[][] arguments
   )
```

renameMonitors(names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename these monitors.

```
   void renameMonitors(
      String[] names
      String[] new_names
   )
```

setAuthentication(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the authentication (user:password) that each of the named monitors should use in the test HTTP request.

```
   void setAuthentication(
      String[] names
      String[] values
   )
```

setAuthenticationByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the authentication (user:password) that each of the named monitors should use in the test HTTP request. This is a location specific function, any action will operate on the specified location.

```
void setAuthenticationByLocation(
   String location
   String[] names
   String[] values
)
```

setBackOff(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should back-off after it has failed.

```
void setBackOff(
   String[] names
   Boolean[] values
)
```

setBackOffByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should back-off after it has failed. This is a location specific function, any action will operate on the specified location.

```
void setBackOffByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setBodyRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that that each of the named monitors' HTTP response must match.

```
void setBodyRegex(
   String[] names
   String[] values
)
```

setBodyRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that that each of the named monitors' HTTP response must match. This is a location specific function, any action will operate on the specified location.

```
void setBodyRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setCloseString(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set an optional string that each of the named monitors should write to the server before closing the connection.

```
void setCloseString(
   String[] names
   String[] values
)
```

setCloseStringByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set an optional string that each of the named monitors should write to the server before closing the connection. This is a location specific function, any action will operate on the specified location.

```
void setCloseStringByLocation(
   String location
   String[] names
   String[] values
)
```

setDelay(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the minimum time between calls to each of the named monitors (in seconds).

```
void setDelay(
   String[] names
   Unsigned Integer[] values
)
```

setDelayByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the minimum time between calls to each of the named monitors (in seconds). This is a location specific function, any action will operate on the specified location.

```
void setDelayByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setFailures(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the number of failures required, by each of the named monitors, before a node is classed as unavailable.

```
void setFailures(
    String[] names
    Unsigned Integer[] values
)
```

setFailuresByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the number of failures required, by each of the named monitors, before a node is classed as unavailable. This is a location specific function, any action will operate on the specified location.

```
void setFailuresByLocation(
    String location
    String[] names
    Unsigned Integer[] values
)
```

setHealthOnly(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should monitor health only (ignore load).

```
void setHealthOnly(
    String[] names
    Boolean[] values
)
```

setHealthOnlyByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should monitor health only (ignore load). This is a location specific function, any action will operate on the specified location.

```
void setHealthOnlyByLocation(
    String location
    String[] names
    Boolean[] values
)
```

setHostHeader(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the host header that each of the named monitors should use in the test HTTP request.

```
void setHostHeader(
    String[] names
    String[] values
)
```

setHostHeaderByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the host header that each of the named monitors should use in the test HTTP request. This is a location specific function, any action will operate on the specified location.

```
void setHostHeaderByLocation(
    String location
    String[] names
    String[] values
)
```

setMachine(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the machine that each of the named monitors should monitor (must be a valid hostname:port or a hostname for Ping monitors).

```
void setMachine(
    String[] names
    String[] values
)
```

setMachineByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the machine that each of the named monitors should monitor (must be a valid hostname:port or a hostname for Ping monitors). This is a location specific function, any action will operate on the specified location.

```
void setMachineByLocation(
   String location
   String[] names
   String[] values
)
```

setMaxResponseLen(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the maximum amount of data (in bytes) that each of the named monitors should read back from a server (0 = unlimited).

```
void setMaxResponseLen(
   String[] names
   Unsigned Integer[] values
)
```

setMaxResponseLenByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the maximum amount of data (in bytes) that each of the named monitors should read back from a server (0 = unlimited). This is a location specific function, any action will operate on the specified location.

```
void setMaxResponseLenByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setNote(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the note for each of the named Monitors.

```
void setNote(
   String[] names
   String[] values
)
```

setPath(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the path that each of the named monitors should use in the test HTTP request.

```
void setPath(
   String[] names
   String[] values
)
```

setPathByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the path that each of the named monitors should use in the test HTTP request. This is a location specific function, any action will operate on the specified location.

```
void setPathByLocation(
   String location
   String[] names
   String[] values
)
```

setProgram(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the name of the program that each named monitor runs.

```
void setProgram(
   String[] names
   String[] values
)
```

setResponseRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the regular expression that each of the named monitors should match against the server response.

```
void setResponseRegex(
   String[] names
   String[] values
)
```

setResponseRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the regular expression that each of the named monitors should match against the server response. This is a location specific function, any action will operate on the specified location.

```
void setResponseRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setRtspBodyRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that each of the named monitors' RTSP response must match.

```
void setRtspBodyRegex(
   String[] names
   String[] values
)
```

setRtspBodyRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that each of the named monitors' RTSP response must match. This is a location specific function, any action will operate on the specified location.

```
void setRtspBodyRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setRtspPath(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the path that each of the named monitors should use in the test RTSP request.

```
void setRtspPath(
   String[] names
   String[] values
)
```

setRtspPathByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the path that each of the named monitors should use in the test RTSP request. This is a location specific function, any action will operate on the specified location.

```
void setRtspPathByLocation(
   String location
   String[] names
   String[] values
)
```

setRtspStatusRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that each of the named monitors' RTSP response must match.

```
void setRtspStatusRegex(
   String[] names
   String[] values
)
```

setRtspStatusRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that each of the named monitors' RTSP response must match. This is a location specific function, any action will operate on the specified location.

```
void setRtspStatusRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setScope(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the scope of each named monitor.

```
void setScope(
   String[] names
   Catalog.Monitor.Scope[] values
)
```

setSipBodyRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that that each of the named monitors' SIP response must match.

```
void setSipBodyRegex(
   String[] names
   String[] values
)
```

setSipBodyRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the body regular expression that that each of the named monitors' SIP response must match. This is a location specific function, any action will operate on the specified location.

```
void setSipBodyRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setSipStatusRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that that each of the named monitors' SIP response must match.

```
void setSipStatusRegex(
   String[] names
   String[] values
)
```

setSipStatusRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that that each of the named monitors' SIP response must match. This is a location specific function, any action will operate on the specified location.

```
void setSipStatusRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setSipTransport(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the transport protocol that the monitor will use

```
void setSipTransport(
   String[] names
   Catalog.Monitor.SipTransport[] values
)
```

setSipTransportByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the transport protocol that the monitor will use This is a location specific function, any action will operate on the specified location.

```
void setSipTransportByLocation(
   String location
   String[] names
   Catalog.Monitor.SipTransport[] values
)
```

setStatusRegex(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that that each of the named monitors' HTTP response must match.

```
void setStatusRegex(
   String[] names
   String[] values
)
```

setStatusRegexByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the status code regular expression that that each of the named monitors' HTTP response must match. This is a location specific function, any action will operate on the specified location.

```
void setStatusRegexByLocation(
   String location
   String[] names
   String[] values
)
```

setTimeout(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the maximum time that an individual instance, of each of the named monitors, is allowed to run for (in seconds).

```
void setTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setTimeoutByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the maximum time that an individual instance, of each of the named monitors, is allowed to run for (in seconds). This is a location specific function, any action will operate on the specified location.

```
void setTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setType(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the internal monitor type to use for each named monitor.

```
void setType(
   String[] names
   Catalog.Monitor.Type[] values
)
```

setUDPAcceptAll(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set if the monitor should accept responses from any IP and port. UDP monitors only.

```
void setUDPAcceptAll(
   String[] names
   Boolean[] values
)
```

setUDPAcceptAllByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set if the monitor should accept responses from any IP and port. UDP monitors only. This is a location specific function, any action will operate on the specified location.

```
void setUDPAcceptAllByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setUseSSL(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors can connect using SSL.

```
void setUseSSL(
   String[] names
   Boolean[] values
)
```

setUseSSLByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors can connect using SSL. This is a location specific function, any action will operate on the specified location.

```
void setUseSSLByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setVerbose(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should emit verbose logging (useful for diagnostics).

```
void setVerbose(
   String[] names
   Boolean[] values
)
```

setVerboseByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set whether each of the named monitors should emit verbose logging (useful for diagnostics). This is a location specific function, any action will operate on the specified location.

```
void setVerboseByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setWriteString(names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the string that each of the named monitors should write down the TCP connection.

```
void setWriteString(
   String[] names
   String[] values
)
```

setWriteStringByLocation(location, names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Set the string that each of the named monitors should write down the TCP connection. This is a location specific function, any action will operate on the specified location.

```
void setWriteStringByLocation(
   String location
   String[] names
   String[] values
)
```

updateProgramArguments(names, argument_names, new_arguments) throws ObjectDoesNotExist, DeploymentError, InvalidInput, InvalidOperation

Allows arguments for the the specified monitors to be changed. The monitors specified must be of type 'program'.

```
void updateProgramArguments(
   String[] names
   String[][] argument_names
   Catalog.Monitor.Argument[][] new_arguments
)
```

uploadMonitorProgram(name, content) throws InvalidObjectName, DeploymentError

Uploads a monitor program, overwriting the file if it already exists.

```
void uploadMonitorProgram(
   String name
   Binary Data content
)
```

6.6.2 Structures

Catalog.Monitor.Argument

An argument that is added to the command line when the monitor program is run

```
struct Catalog.Monitor.Argument {
   # The name of the argument.
   String name;

   # The value of the argument.
   String value;

   # A description of the argument.
   String description;
}
```

6.6.3 Enumerations

Catalog.Monitor.Scope

```
enum Catalog.Monitor.Scope {
   # Node: Monitor each node in the pool separately
   pernode,

   # Pool/GLB: Monitor a specified machine
   poolwide
}
```

Catalog.Monitor.SipTransport

```
enum Catalog.Monitor.SipTransport {
   # UDP
   udp,

   # TCP
   tcp
}
```

Catalog.Monitor.Type

```
enum Catalog.Monitor.Type {
   # Ping monitor
   ping,

   # TCP Connect monitor
   connect,

   # HTTP monitor
   http,

   # TCP transaction monitor
   tcp_transaction,

   # External program monitor
   program,

   # SIP monitor
   sip,

   # RTSP monitor
   rtsp
}
```

6.7 Catalog.SSL.Certificates

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/SSL/Certificates/`

The Catalog.SSL.Certificates interface allows management of SSL Certificates which are used for SSL decryption of services. Using this interface, you can create, delete and rename SSL Certificate objects.

6.7.1 Methods

createSelfSignedCertificate(names, details) throws InvalidObjectName, ObjectAlreadyExists, InvalidInput, DeploymentError

Create new self-signed certificates.

```
void createSelfSignedCertificate(
   String[] names
   Catalog.SSL.Certificates.CertificateDetails[] details
)
```

deleteCertificate(names) throws InvalidObjectName, ObjectDoesNotExist

Delete the named certificates.

```
void deleteCertificate(
    String[] names
)
```

getCertificateInfo(names) throws ObjectDoesNotExist

Get the information about the namedcertificates.

```
Certificate[] getCertificateInfo(
    String[] names
)
```

getCertificateNames()

Get the names of the installed certificates.

```
String[] getCertificateNames()
```

getCertificateRequest(names) throws ObjectDoesNotExist

Get Certificate signing requests for the named certificates.

```
String[] getCertificateRequest(
    String[] names
)
```

getRawCertificate(names) throws ObjectDoesNotExist

Get the raw (PEM-encoded) certificates.

```
String[] getRawCertificate(
    String[] names
)
```

importCertificate(names, keys) throws InvalidObjectName, ObjectAlreadyExists, InvalidInput

Create a new certificate, importing the certificate and private key.

```
void importCertificate(
    String[] names
    CertificateFiles[] keys
)
```

renameCertificate(names, new_names) throws InvalidObjectName, ObjectAlreadyExists, ObjectDoesNotExist

Rename the named certificates.

```
void renameCertificate(
   String[] names
   String[] new_names
)
```

setRawCertificate(names, certs) throws ObjectDoesNotExist

Set the (PEM-encoded) certificate. This should be used after getting a Certificate request signed by a certificate authority.

```
void setRawCertificate(
   String[] names
   String[] certs
)
```

6.7.2 Structures

Catalog.SSL.Certificates.CertificateDetails

This structure contains the information used when generating self-signed test certificates.

```
struct Catalog.SSL.Certificates.CertificateDetails {
   # The subject of the new certificate. The common_name of the
   # subject should match the DNS name of the service this
   # certificate is to be used for.
   X509Name subject;

   # The number of days this certificate should be value for
   # (e.g. 365 for 1 years validity)
   Integer valid_days;

   # The size of the generated private key. Use 1024 for normal
   # use, or 2048 for more security
   Integer key_size;
}
```

Certificate

This structure contains information (such as the subject and issuer) about a certificate.

```
struct Certificate {
   # The version of the X509 Certificate
   Integer version;

   # The serial number of the Certificate
   String serial;

   # The issuer (i.e. who signed it) of the Certificate
   X509Name issuer;
```

```
    # The subject (i.e. who it is for) of the Certificate
    X509Name subject;

    # The time the certificate is valid from.
    Time valid_from;

    # The time the certificate is valid to.
    Time valid_to;

    # The modulus of the certificate.
    String modulus;

    # The exponent of the certificate.
    String exponent;

    # Whether the certificate is self-signed (i.e. the issuer is
    # the same as the subject)
    Boolean self_signed;
}
```

CertificateFiles

This structure contains a public certificate and private key. It is used when importing certificates into the traffic manager.

```
struct CertificateFiles {
    # The PEM-encoded public certificate (containing the BEGIN
    # CERTIFICATE and END CERTIFICATE tags)
    String public_cert;

    # The PEM-encoded private key (containing the BEGIN RSA
    # PRIVATE KEY and END RSA PRIVATE KEY tags)
    String private_key;
}
```

X509Name

This structure contains a representation of an X509 Name object. These are used inside Certificate objects to represent the issuer and subject of the certificate.

```
struct X509Name {
    # The common name (CN). This is usually the name of the site
    # the certificate is issued to (e.g. "secure.example.com")
    String common_name;

    # The two-letter country code.
    String country;

    # The location (town or city).
    String location;
```

```
# The state, this is only needed if the country is 'US'.
String state;

# The name of the organisation
String organisation;

# The unit inside the organisation
String unit;

# An email address. This is usually empty.
String email;
}
```

6.8   Catalog.SSL.CertificateAuthorities

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/SSL/CertificateAuthorities/`

The Catalog.SSL.CertificateAuthorities interface allows management of SSL Certificate Authorities which are used to authenticate back-end nodes when doing SSL encryption.

6.8.1   Methods

deleteCertificateAuthority(names) throws ObjectDoesNotExist

Delete the named Certificate Authority and associated Revocation list.

```
void deleteCertificateAuthority(
   String[] names
)
```

getCertificateAuthorityInfo(names) throws ObjectDoesNotExist

Get the Certificate Information, and the revoked certificates.

```
Catalog.SSL.CertificateAuthorities.Details[]
getCertificateAuthorityInfo(
   String[] names
)
```

getCertificateAuthorityNames()

Get the names of the configured Certificate Authorities.

```
String[] getCertificateAuthorityNames()
```

getRawCertificate(names) throws ObjectDoesNotExist

Get the raw PEM encoded Certificate for the named Certificate Authorities.

```
String[] getRawCertificate(
   String[] names
)
```

importCRL(crls) throws InvalidInput, ObjectDoesNotExist

Import Certificate Revocation Lists. The associated Certificate Authority certificates should already be imported.

```
void importCRL(
   String[] crls
)
```

importCertificateAuthority(names, certs) throws InvalidObjectName, ObjectAlreadyExists, InvalidInput

Import new Certificate Authorities.

```
void importCertificateAuthority(
   String[] names
   String[] certs
)
```

renameCertificateAuthority(names, new_names) throws InvalidObjectName, ObjectDoesNotExist, ObjectAlreadyExists, InvalidOperation

Rename the named Certificate Authorities.

```
void renameCertificateAuthority(
   String[] names
   String[] new_names
)
```

6.8.2 Structures

Catalog.SSL.CertificateAuthorities.CRL

This structure contains the information about a Certificate Revocation list.

```
struct Catalog.SSL.CertificateAuthorities.CRL {
   # The time when the CRL was updated
   Time update;

   # The time that the CRL will next be updated.
   Time next_update;
```

```
      # The list of revoked certificates
      Catalog.SSL.CertificateAuthorities.RevokedCert[] revoked_certs;
}
```

Catalog.SSL.CertificateAuthorities.Details

This structure contains the information about a Certificate Authority. It contains both the Certificate, and the list of revoked Certificates contained in the associated CRL.

```
struct Catalog.SSL.CertificateAuthorities.Details {
   # The Certificate Authority certificate
   Certificate certificate;

   # If set to 'true' then there is an associated CRL, otherwise
   # the CRL structure contains no useful information
   Boolean have_crl;

   # The associated CRL.
   Catalog.SSL.CertificateAuthorities.CRL crl;
}
```

Catalog.SSL.CertificateAuthorities.RevokedCert

This structure contains the information about a revoked Certificate.

```
struct Catalog.SSL.CertificateAuthorities.RevokedCert {
   # The serial number of the revoked certificate
   String serial;

   # The time that the certificate was revoked
   Time revocation_date;
}
```

Certificate

This structure contains information (such as the subject and issuer) about a certificate.

```
struct Certificate {
   # The version of the X509 Certificate
   Integer version;

   # The serial number of the Certificate
   String serial;

   # The issuer (i.e. who signed it) of the Certificate
   X509Name issuer;

   # The subject (i.e. who it is for) of the Certificate
   X509Name subject;
```

```
    # The time the certificate is valid from.
    Time valid_from;

    # The time the certificate is valid to.
    Time valid_to;

    # The modulus of the certificate.
    String modulus;

    # The exponent of the certificate.
    String exponent;

    # Whether the certificate is self-signed (i.e. the issuer is
    # the same as the subject)
    Boolean self_signed;
}
```

CertificateFiles

This structure contains a public certificate and private key. It is used when importing certificates into the traffic manager.

```
struct CertificateFiles {
    # The PEM-encoded public certificate (containing the BEGIN
    # CERTIFICATE and END CERTIFICATE tags)
    String public_cert;

    # The PEM-encoded private key (containing the BEGIN RSA
    # PRIVATE KEY and END RSA PRIVATE KEY tags)
    String private_key;
}
```

X509Name

This structure contains a representation of an X509 Name object. These are used inside Certificate objects to represent the issuer and subject of the certificate.

```
struct X509Name {
    # The common name (CN). This is usually the name of the site
    # the certificate is issued to (e.g. "secure.example.com")
    String common_name;

    # The two-letter country code.
    String country;

    # The location (town or city).
    String location;

    # The state, this is only needed if the country is 'US'.
```

```
        String state;

        # The name of the organisation
        String organisation;

        # The unit inside the organisation
        String unit;

        # An email address. This is usually empty.
        String email;
    }
```

6.9   Catalog.SSL.ClientCertificates

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/SSL/ClientCertificates/`

The Catalog.SSL.ClientCertificates interface allows management of SSL Client Certificates which are for authentication with back-end nodes when encrypting services. This interfaces allows you to import, retrieve, rename and delete the SSL Client Certificate objects

6.9.1   Methods

deleteClientCertificate(names) throws ObjectDoesNotExist

Delete the named client certificates.

```
void deleteClientCertificate(
    String[] names
)
```

getClientCertificateInfo(names) throws ObjectDoesNotExist

Gets the information about the named client certificates.

```
Certificate[] getClientCertificateInfo(
    String[] names
)
```

getClientCertificateNames()

Get the names of the installed client certificates.

```
String[] getClientCertificateNames()
```

importClientCertificate(names, keys) throws InvalidObjectName, ObjectAlreadyExists, InvalidInput

Import client certificates and associated private keys.

```
void importClientCertificate(
    String[] names
    CertificateFiles[] keys
)
```

renameClientCertificate(names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, DeploymentError

Rename the named client certificates.

```
void renameClientCertificate(
    String[] names
    String[] new_names
)
```

6.9.2 Structures

Certificate

This structure contains information (such as the subject and issuer) about a certificate.

```
struct Certificate {
    # The version of the X509 Certificate
    Integer version;

    # The serial number of the Certificate
    String serial;

    # The issuer (i.e. who signed it) of the Certificate
    X509Name issuer;

    # The subject (i.e. who it is for) of the Certificate
    X509Name subject;

    # The time the certificate is valid from.
    Time valid_from;

    # The time the certificate is valid to.
    Time valid_to;

    # The modulus of the certificate.
    String modulus;

    # The exponent of the certificate.
    String exponent;

    # Whether the certificate is self-signed (i.e. the issuer is
    # the same as the subject)
    Boolean self_signed;
}
```

CertificateFiles

This structure contains a public certificate and private key. It is used when importing certificates into the traffic manager.

```
struct CertificateFiles {
    # The PEM-encoded public certificate (containing the BEGIN
    # CERTIFICATE and END CERTIFICATE tags)
    String public_cert;

    # The PEM-encoded private key (containing the BEGIN RSA
    # PRIVATE KEY and END RSA PRIVATE KEY tags)
    String private_key;
}
```

X509Name

This structure contains a representation of an X509 Name object. These are used inside Certificate objects to represent the issuer and subject of the certificate.

```
struct X509Name {
    # The common name (CN). This is usually the name of the site
    # the certificate is issued to (e.g. "secure.example.com")
    String common_name;

    # The two-letter country code.
    String country;

    # The location (town or city).
    String location;

    # The state, this is only needed if the country is 'US'.
    String state;

    # The name of the organisation
    String organisation;

    # The unit inside the organisation
    String unit;

    # An email address. This is usually empty.
    String email;
}
```

6.10 Catalog.SSL.DNSSEC

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/SSL/DNSSEC/`

The Catalog.SSL.DNSSEC interface allows management of the DNSSEC private keys used to alter signed GLB DNS responses.

6.10.1 Methods

addKeysWithManualIDs(names, keys, ids) throws ObjectAlreadyExists, InvalidObjectName, InvalidInput

Upload a DNSSEC private key to the traffic manager's catalog. Each key string should be the contents of your private key file. The ID of the key is the third set of parameters.

```
void addKeysWithManualIDs(
   String[] names
   String[] keys
   Integer[] ids
)
```

addStandardKeys(names, keys) throws ObjectAlreadyExists, InvalidObjectName, InvalidInput

Upload a DNSSEC private key to the traffic manager's catalog. Each key string should be the contents of your private key file. The ID of the key will be calculated assuming it is a standard ZSK.

```
void addStandardKeys(
   String[] names
   String[] keys
)
```

deleteKeys(names) throws ObjectDoesNotExist, DeploymentError

Delete the specified DNSSEC keys.

```
void deleteKeys(
   String[] names
)
```

getKeyIDs(names) throws ObjectDoesNotExist

Get the IDs of the specified DNSSEC private keys.

```
Integer[] getKeyIDs(
   String[] names
)
```

getKeyNames()

Get the names of the installed DNSSEC private keys.

```
String[] getKeyNames()
```

renameKeys(names, new_names) throws ObjectDoesNotExist, InvalidInput, InvalidObjectName, ObjectAlreadyExists, DeploymentError

Rename the specified DNSSEC keys.

```
void renameKeys(
   String[] names
   String[] new_names
)
```

6.11 Catalog.Protection

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/Protection/`

The Catalog.Protection interface allows management of Service Protection classes. Using this interface, you can create, delete and rename Protection classes, and manage their configuration.

6.11.1 Methods

addAllowedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new IP addresses and CIDR IP subnets to the list of machines that are always allowed access.

```
void addAllowedAddresses(
   String[] class_names
   String[][] values
)
```

addAllowedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new IP addresses and CIDR IP subnets to the list of machines that are always allowed access. This is a location specific function, any action will operate on the specified location.

```
void addAllowedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

addBannedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new IP addresses and CIDR IP subnets to the list of machines that aren't allowed access.

```
void addBannedAddresses(
   String[] class_names
   String[][] values
)
```

addBannedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Add new IP addresses and CIDR IP subnets to the list of machines that aren't allowed access. This is a location specific function, any action will operate on the specified location.

```
void addBannedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

addProtection(class_names) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError

Add new Protection classes.

```
void addProtection(
   String[] class_names
)
```

copyProtection(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Copy the named Protection classes.

```
void copyProtection(
   String[] class_names
   String[] new_names
)
```

deleteProtection(class_names) throws ObjectInUse, ObjectDoesNotExist, DeploymentError

Delete the named Protection classes.

```
void deleteProtection(
   String[] class_names
```

)

getAllowedAddresses(class_names) throws ObjectDoesNotExist

Get the list of IP addresses and CIDR IP subnets that are always allowed access.

```
String[][] getAllowedAddresses(
   String[] class_names
)
```

getAllowedAddressesByLocation(location, class_names) throws ObjectDoesNotExist

Get the list of IP addresses and CIDR IP subnets that are always allowed access. This is a location specific function, any action will operate on the specified location.

```
String[][] getAllowedAddressesByLocation(
   String location
   String[] class_names
)
```

getBannedAddresses(class_names) throws ObjectDoesNotExist

Get the list of IP addresses and CIDR IP subnets that aren't allowed access.

```
String[][] getBannedAddresses(
   String[] class_names
)
```

getBannedAddressesByLocation(location, class_names) throws ObjectDoesNotExist

Get the list of IP addresses and CIDR IP subnets that aren't allowed access. This is a location specific function, any action will operate on the specified location.

```
String[][] getBannedAddressesByLocation(
   String location
   String[] class_names
)
```

getDebug(class_names) throws ObjectDoesNotExist

Get whether the service protection classes are in debug mode. When in debug mode, verbose log messages are written.

```
Boolean[] getDebug(
   String[] class_names
)
```

getDebugByLocation(location, class_names) throws ObjectDoesNotExist

Get whether the service protection classes are in debug mode. When in debug mode, verbose log messages are written. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getDebugByLocation(
   String location
   String[] class_names
)
```

getEnabled(class_names) throws ObjectDoesNotExist

Get whether the service protection classes are enabled.

```
Boolean[] getEnabled(
   String[] class_names
)
```

getEnabledByLocation(location, class_names) throws ObjectDoesNotExist

Get whether the service protection classes are enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getEnabledByLocation(
   String location
   String[] class_names
)
```

getHTTPCheckRfc2396(class_names) throws ObjectDoesNotExist

Get whether requests with poorly-formed URLs (as specified in RFC 2396) should be rejected.

```
Boolean[] getHTTPCheckRfc2396(
   String[] class_names
)
```

getHTTPCheckRfc2396ByLocation(location, class_names) throws ObjectDoesNotExist

Get whether requests with poorly-formed URLs (as specified in RFC 2396) should be rejected. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getHTTPCheckRfc2396ByLocation(
   String location
```

```
    String[] class_names
)
```

getHTTPRejectBinary(class_names) throws ObjectDoesNotExist

Get whether requests containing binary data (after decoding) should be rejected.

```
Boolean[] getHTTPRejectBinary(
    String[] class_names
)
```

getHTTPRejectBinaryByLocation(location, class_names) throws ObjectDoesNotExist

Get whether requests containing binary data (after decoding) should be rejected. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getHTTPRejectBinaryByLocation(
    String location
    String[] class_names
)
```

getHTTPSendErrorPage(class_names) throws ObjectDoesNotExist

Get whether an HTTP error message should be sent when a connection is dropped, rather than just dropping the connection.

```
Boolean[] getHTTPSendErrorPage(
    String[] class_names
)
```

getHTTPSendErrorPageByLocation(location, class_names) throws ObjectDoesNotExist

Get whether an HTTP error message should be sent when a connection is dropped, rather than just dropping the connection. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getHTTPSendErrorPageByLocation(
    String location
    String[] class_names
)
```

getLogInterval(class_names) throws ObjectDoesNotExist

Get the interval between logging service protection messages (in seconds).

```
Unsigned Integer[] getLogInterval(
```

```
      String[] class_names
   )
```

getLogIntervalByLocation(location, class_names) throws ObjectDoesNotExist

Get the interval between logging service protection messages (in seconds). This is a location specific function, any action will operate on the specified location.

```
   Unsigned Integer[] getLogIntervalByLocation(
      String location
      String[] class_names
   )
```

getMax10Connections(class_names) throws ObjectDoesNotExist

Get the maximum number of simultaneous connections allowed from the 10 busiest IP addresses.

```
   Unsigned Integer[] getMax10Connections(
      String[] class_names
   )
```

getMax10ConnectionsByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum number of simultaneous connections allowed from the 10 busiest IP addresses. This is a location specific function, any action will operate on the specified location.

```
   Unsigned Integer[] getMax10ConnectionsByLocation(
      String location
      String[] class_names
   )
```

getMax1Connections(class_names) throws ObjectDoesNotExist

Get the maximum number of simultaneous connections allowed from an individual IP address.

```
   Unsigned Integer[] getMax1Connections(
      String[] class_names
   )
```

getMax1ConnectionsByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum number of simultaneous connections allowed from an individual IP address. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMax1ConnectionsByLocation(
   String location
   String[] class_names
)
```

getMaxConnectionRate(class_names) throws ObjectDoesNotExist

Get the maximum number of connections and HTTP keepalive requests allowed from 1 IP address in the 'rate_timer' interval (0 means unlimited).

```
Unsigned Integer[] getMaxConnectionRate(
   String[] class_names
)
```

getMaxConnectionRateByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum number of connections and HTTP keepalive requests allowed from 1 IP address in the 'rate_timer' interval (0 means unlimited). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxConnectionRateByLocation(
   String location
   String[] class_names
)
```

getMaxHTTPBodyLength(class_names) throws ObjectDoesNotExist

Get the maximum size of the HTTP request body data (in bytes, 0 means no limit).

```
Unsigned Integer[] getMaxHTTPBodyLength(
   String[] class_names
)
```

getMaxHTTPBodyLengthByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum size of the HTTP request body data (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxHTTPBodyLengthByLocation(
   String location
```

```
   String[] class_names
)
```

getMaxHTTPHeaderLength(class_names) throws ObjectDoesNotExist

Get the maximum size of a single HTTP request header (in bytes, 0 means no limit).

```
Unsigned Integer[] getMaxHTTPHeaderLength(
   String[] class_names
)
```

getMaxHTTPHeaderLengthByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum size of a single HTTP request header (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxHTTPHeaderLengthByLocation(
   String location
   String[] class_names
)
```

getMaxHTTPRequestLength(class_names) throws ObjectDoesNotExist

Get the maximum size of all the HTTP request headers (in bytes, 0 means no limit).

```
Unsigned Integer[] getMaxHTTPRequestLength(
   String[] class_names
)
```

getMaxHTTPRequestLengthByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum size of all the HTTP request headers (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxHTTPRequestLengthByLocation(
   String location
   String[] class_names
)
```

getMaxHTTPURLLength(class_names) throws ObjectDoesNotExist

Get the maximum size of the request URL (in bytes, 0 means no limit).

```
Unsigned Integer[] getMaxHTTPURLLength(
   String[] class_names
)
```

getMaxHTTPURLLengthByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum size of the request URL (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxHTTPURLLengthByLocation(
   String location
   String[] class_names
)
```

getMinConnections(class_names) throws ObjectDoesNotExist

Get the number of simultaneous connections that are always allowed from each IP address (0 means unlimited).

```
Unsigned Integer[] getMinConnections(
   String[] class_names
)
```

getMinConnectionsByLocation(location, class_names) throws ObjectDoesNotExist

Get the number of simultaneous connections that are always allowed from each IP address (0 means unlimited). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMinConnectionsByLocation(
   String location
   String[] class_names
)
```

getNote(class_names) throws ObjectDoesNotExist

Get the note for each of the named Protection classes

```
String[] getNote(
   String[] class_names
)
```

getProtectionNames()

Get the names of all the configured Protection classes.

```
String[] getProtectionNames()
```

getRateTimer(class_names) throws ObjectDoesNotExist

Get how frequently the max_connection_rate is assessed. For example, a value of 1 second will impose a limit of max connections/second; a value of 60 will impose a limit of max connections/minute controlling how our connection rates are calculated.

```
Unsigned Integer[] getRateTimer(
   String[] class_names
)
```

getRateTimerByLocation(location, class_names) throws ObjectDoesNotExist

Get how frequently the max_connection_rate is assessed. For example, a value of 1 second will impose a limit of max connections/second; a value of 60 will impose a limit of max connections/minute controlling how our connection rates are calculated. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getRateTimerByLocation(
   String location
   String[] class_names
)
```

getRule(class_names) throws ObjectDoesNotExist

Get the TrafficScript rule to be applied to all connections.

```
String[] getRule(
   String[] class_names
)
```

getRuleByLocation(location, class_names) throws ObjectDoesNotExist

Get the TrafficScript rule to be applied to all connections. This is a location specific function, any action will operate on the specified location.

```
String[] getRuleByLocation(
   String location
   String[] class_names
)
```

getTesting(class_names) throws ObjectDoesNotExist

Get whether the service protection classes are in testing mode. When in testing mode the class logs when a connection would be dropped, but it allows all connections through.

```
Boolean[] getTesting(
   String[] class_names
)
```

getTestingByLocation(location, class_names) throws ObjectDoesNotExist

Get whether the service protection classes are in testing mode. When in testing mode the class logs when a connection would be dropped, but it allows all connections through. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getTestingByLocation(
   String location
   String[] class_names
)
```

removeAllowedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Remove IP addresses and CIDR IP subnets from the list of machines that are always allowed access.

```
void removeAllowedAddresses(
   String[] class_names
   String[][] values
)
```

removeAllowedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Remove IP addresses and CIDR IP subnets from the list of machines that are always allowed access. This is a location specific function, any action will operate on the specified location.

```
void removeAllowedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

removeBannedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Remove IP addresses and CIDR IP subnets from the list of machines that aren't allowed access.

```
void removeBannedAddresses(
   String[] class_names
   String[][] values
)
```

removeBannedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Remove IP addresses and CIDR IP subnets from the list of machines that aren't allowed access. This is a location specific function, any action will operate on the specified location.

```
void removeBannedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

renameProtection(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename the named Protection classes.

```
void renameProtection(
   String[] class_names
   String[] new_names
)
```

setAllowedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the list of IP addresses and CIDR IP subnets that are always allowed access.

```
void setAllowedAddresses(
   String[] class_names
   String[][] values
)
```

setAllowedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the list of IP addresses and CIDR IP subnets that are always allowed access. This is a location specific function, any action will operate on the specified location.

```
void setAllowedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

setBannedAddresses(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the list of IP addresses and CIDR IP subnets that aren't allowed access.

```
void setBannedAddresses(
   String[] class_names
   String[][] values
)
```

setBannedAddressesByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the list of IP addresses and CIDR IP subnets that aren't allowed access. This is a location specific function, any action will operate on the specified location.

```
void setBannedAddressesByLocation(
   String location
   String[] class_names
   String[][] values
)
```

setDebug(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are in debug mode. When in debug mode, verbose log messages are written.

```
void setDebug(
   String[] class_names
   Boolean[] values
)
```

setDebugByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are in debug mode. When in debug mode, verbose log messages are written. This is a location specific function, any action will operate on the specified location.

```
void setDebugByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

setEnabled(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are enabled.

```
void setEnabled(
   String[] class_names
```

```
    Boolean[] values
  )
```

setEnabledByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are enabled. This is a location specific function, any action will operate on the specified location.

```
void setEnabledByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

setHTTPCheckRfc2396(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether requests with poorly-formed URLs (as specified in RFC 2396) should be rejected.

```
void setHTTPCheckRfc2396(
   String[] class_names
   Boolean[] values
)
```

setHTTPCheckRfc2396ByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether requests with poorly-formed URLs (as specified in RFC 2396) should be rejected. This is a location specific function, any action will operate on the specified location.

```
void setHTTPCheckRfc2396ByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

setHTTPRejectBinary(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether requests containing binary data (after decoding) should be rejected.

```
void setHTTPRejectBinary(
   String[] class_names
   Boolean[] values
)
```

setHTTPRejectBinaryByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether requests containing binary data (after decoding) should be rejected. This is a location specific function, any action will operate on the specified location.

```
void setHTTPRejectBinaryByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

setHTTPSendErrorPage(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether an HTTP error message should be sent when a connection is dropped, rather than just dropping the connection.

```
void setHTTPSendErrorPage(
   String[] class_names
   Boolean[] values
)
```

setHTTPSendErrorPageByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether an HTTP error message should be sent when a connection is dropped, rather than just dropping the connection. This is a location specific function, any action will operate on the specified location.

```
void setHTTPSendErrorPageByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

setLogInterval(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the interval between logging service protection messages (in seconds).

```
void setLogInterval(
   String[] class_names
   Unsigned Integer[] values
)
```

setLogIntervalByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the interval between logging service protection messages (in seconds). This is a location specific function, any action will operate on the specified location.

```
void setLogIntervalByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMax10Connections(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of simultaneous connections allowed from the 10 busiest IP addresses.

```
void setMax10Connections(
   String[] class_names
   Unsigned Integer[] values
)
```

setMax10ConnectionsByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of simultaneous connections allowed from the 10 busiest IP addresses. This is a location specific function, any action will operate on the specified location.

```
void setMax10ConnectionsByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMax1Connections(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of simultaneous connections allowed from an individual IP address.

```
void setMax1Connections(
   String[] class_names
   Unsigned Integer[] values
)
```

setMax1ConnectionsByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of simultaneous connections allowed from an individual IP address. This is a location specific function, any action will operate on the specified location.

```
void setMax1ConnectionsByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxConnectionRate(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of connections and HTTP keepalive requests allowed from 1 IP address in the 'rate_timer' interval (0 means unlimited).

```
void setMaxConnectionRate(
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxConnectionRateByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum number of connections and HTTP keepalive requests allowed from 1 IP address in the 'rate_timer' interval (0 means unlimited). This is a location specific function, any action will operate on the specified location.

```
void setMaxConnectionRateByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxHTTPBodyLength(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of the HTTP request body data (in bytes, 0 means no limit).

```
void setMaxHTTPBodyLength(
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxHTTPBodyLengthByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of the HTTP request body data (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
void setMaxHTTPBodyLengthByLocation(
    String location
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxHTTPHeaderLength(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of a single HTTP request header (in bytes, 0 means no limit).

```
void setMaxHTTPHeaderLength(
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxHTTPHeaderLengthByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of a single HTTP request header (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
void setMaxHTTPHeaderLengthByLocation(
    String location
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxHTTPRequestLength(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of all the HTTP request headers (in bytes, 0 means no limit).

```
void setMaxHTTPRequestLength(
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxHTTPRequestLengthByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of all the HTTP request headers (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
void setMaxHTTPRequestLengthByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxHTTPURLLength(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of the request URL (in bytes, 0 means no limit).

```
void setMaxHTTPURLLength(
   String[] class_names
   Unsigned Integer[] values
)
```

setMaxHTTPURLLengthByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the maximum size of the request URL (in bytes, 0 means no limit). This is a location specific function, any action will operate on the specified location.

```
void setMaxHTTPURLLengthByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setMinConnections(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the number of simultaneous connections that are always allowed from each IP address (0 means unlimited).

```
void setMinConnections(
   String[] class_names
   Unsigned Integer[] values
)
```

setMinConnectionsByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the number of simultaneous connections that are always allowed from each IP address (0 means unlimited). This is a location specific function, any action will operate on the specified location.

```
void setMinConnectionsByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setNote(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the note for each of the named Protection classes

```
void setNote(
   String[] class_names
   String[] values
)
```

setRateTimer(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set how frequently the max_connection_rate is assessed. For example, a value of 1 second will impose a limit of max connections/second; a value of 60 will impose a limit of max connections/minute controlling how our connection rates are calculated.

```
void setRateTimer(
   String[] class_names
   Unsigned Integer[] values
)
```

setRateTimerByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set how frequently the max_connection_rate is assessed. For example, a value of 1 second will impose a limit of max connections/second; a value of 60 will impose a limit of max connections/minute controlling how our connection rates are calculated. This is a location specific function, any action will operate on the specified location.

```
void setRateTimerByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setRule(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the TrafficScript rule to be applied to all connections.

```
void setRule(
   String[] class_names
   String[] values
)
```

setRuleByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the TrafficScript rule to be applied to all connections. This is a location specific function, any action will operate on the specified location.

```
void setRuleByLocation(
   String location
   String[] class_names
   String[] values
)
```

setTesting(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are in testing mode. When in testing mode the class logs when a connection would be dropped, but it allows all connections through.

```
void setTesting(
   String[] class_names
   Boolean[] values
)
```

setTestingByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the service protection classes are in testing mode. When in testing mode the class logs when a connection would be dropped, but it allows all connections through. This is a location specific function, any action will operate on the specified location.

```
void setTestingByLocation(
   String location
   String[] class_names
   Boolean[] values
)
```

6.12 Catalog.Persistence

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/Persistence/`

The Catalog.Persistence interface allows management of Persistence classes. Using this interface, you can create, delete and rename persistence classes, and manage their configuration.

6.12.1 Methods

addPersistence(class_names) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError

Add new persistence classes.

```
void addPersistence(
   String[] class_names
)
```

copyPersistence(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Copy the named persistence classes.

```
void copyPersistence(
   String[] class_names
   String[] new_names
)
```

deletePersistence(class_names) throws ObjectDoesNotExist, ObjectInUse, DeploymentError

Delete the named persistence classes.

```
void deletePersistence(
   String[] class_names
)
```

getCookie(class_names) throws ObjectDoesNotExist

Get the name of the cookie used to track session persistence.

```
String[] getCookie(
   String[] class_names
)
```

getCookieByLocation(location, class_names) throws ObjectDoesNotExist

Get the name of the cookie used to track session persistence. This is a location specific function, any action will operate on the specified location.

```
String[] getCookieByLocation(
   String location
   String[] class_names
)
```

getDelete(class_names) throws ObjectDoesNotExist

Get whether the session should be deleted if a failure occurs.

```
Boolean[] getDelete(
   String[] class_names
)
```

getDeleteByLocation(location, class_names) throws ObjectDoesNotExist

Get whether the session should be deleted if a failure occurs. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getDeleteByLocation(
   String location
   String[] class_names
)
```

getFailureMode(class_names) throws ObjectDoesNotExist

Get the action that should be taken if the session data is invalid or the node specified cannot be contacted.

```
Catalog.Persistence.FailureMode[] getFailureMode(
   String[] class_names
)
```

getFailureModeByLocation(location, class_names) throws ObjectDoesNotExist

Get the action that should be taken if the session data is invalid or the node specified cannot be contacted. This is a location specific function, any action will operate on the specified location.

```
Catalog.Persistence.FailureMode[] getFailureModeByLocation(
   String location
   String[] class_names
)
```

getNote(class_names) throws ObjectDoesNotExist

Get the note for each of the named Session Persistence classes.

```
String[] getNote(
   String[] class_names
)
```

getPersistenceNames()

Get the names of all the configured persistence classes.

```
String[] getPersistenceNames()
```

getType(class_names) throws ObjectDoesNotExist

Gets the session method type.

```
Catalog.Persistence.Type[] getType(
   String[] class_names
)
```

getTypeByLocation(location, class_names) throws ObjectDoesNotExist

Gets the session method type. This is a location specific function, any action will operate on the specified location.

```
Catalog.Persistence.Type[] getTypeByLocation(
   String location
   String[] class_names
)
```

getUrl(class_names) throws ObjectDoesNotExist

Get the URL to send to clients if the session persistence is configured to redirect users when a node dies.

```
String[] getUrl(
   String[] class_names
)
```

getUrlByLocation(location, class_names) throws ObjectDoesNotExist

Get the URL to send to clients if the session persistence is configured to redirect users when a node dies. This is a location specific function, any action will operate on the specified location.

```
String[] getUrlByLocation(
   String location
```

```
   String[] class_names
)
```

renamePersistence(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename the named persistence classes.

```
void renamePersistence(
   String[] class_names
   String[] new_names
)
```

setCookie(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the name of the cookie used to track session persistence.

```
void setCookie(
   String[] class_names
   String[] values
)
```

setCookieByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the name of the cookie used to track session persistence. This is a location specific function, any action will operate on the specified location.

```
void setCookieByLocation(
   String location
   String[] class_names
   String[] values
)
```

setDelete(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the session should be deleted if a failure occurs.

```
void setDelete(
   String[] class_names
   Boolean[] values
)
```

setDeleteByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set whether the session should be deleted if a failure occurs. This is a location specific function, any action will operate on the specified location.

```
void setDeleteByLocation(
    String location
    String[] class_names
    Boolean[] values
)
```

setFailureMode(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the action that should be taken if the session data is invalid or the node specified cannot be contacted.

```
void setFailureMode(
    String[] class_names
    Catalog.Persistence.FailureMode[] values
)
```

setFailureModeByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the action that should be taken if the session data is invalid or the node specified cannot be contacted. This is a location specific function, any action will operate on the specified location.

```
void setFailureModeByLocation(
    String location
    String[] class_names
    Catalog.Persistence.FailureMode[] values
)
```

setNote(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the note for each of the named Session Persistence classes.

```
void setNote(
    String[] class_names
    String[] values
)
```

setType(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Sets the session method type.

```
void setType(
   String[] class_names
   Catalog.Persistence.Type[] values
)
```

setTypeByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Sets the session method type. This is a location specific function, any action will operate on the specified location.

```
void setTypeByLocation(
   String location
   String[] class_names
   Catalog.Persistence.Type[] values
)
```

setUrl(class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the URL to send to clients if the session persistence is configured to redirect users when a node dies.

```
void setUrl(
   String[] class_names
   String[] values
)
```

setUrlByLocation(location, class_names, values) throws ObjectDoesNotExist, DeploymentError, InvalidInput

Set the URL to send to clients if the session persistence is configured to redirect users when a node dies. This is a location specific function, any action will operate on the specified location.

```
void setUrlByLocation(
   String location
   String[] class_names
   String[] values
)
```

6.12.2 Enumerations

Catalog.Persistence.FailureMode

```
enum Catalog.Persistence.FailureMode {
    # Choose a new node to use
    newnode,

    # Redirect the user to a given URL
    url,

    # Close the connection (using error_file on Virtual Servers >
    # Edit > Connection Management)
    close
}
```

Catalog.Persistence.Type

```
enum Catalog.Persistence.Type {
    # IP-based persistence
    ip,

    # Universal session persistence
    universal,

    # Named Node session persistence
    named,

    # Transparent session affinity
    transparent,

    # Monitor application cookies
    monitor-cookies,

    # J2EE session persistence
    j2ee,

    # ASP and ASP.NET session persistence
    asp,

    # X-Zeus-Backend cookies
    x-zeus,

    # SSL Session ID persistence
    ssl,

    # Deprecated. Use 'monitor-cookies' instead.
    kipper,

    # Deprecated. Use 'transparent' instead.
    sardine
```

```
    }
```

6.13 Catalog.Bandwidth

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/Bandwidth/`

The Catalog.Bandwidth interface allows management of Bandwidth classes. Using this interface, you can create, delete and rename bandwidth classes, and manage their configuration.

6.13.1 Methods

addBandwidth(class_names) throws InvalidOperation, ObjectAlreadyExists, InvalidObjectName, LicenseError, DeploymentError

Add new bandwidth classes.

```
void addBandwidth(
    String[] class_names
)
```

copyBandwidth(class_names, new_names) throws InvalidOperation, ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, LicenseError

Copy the named bandwidth classes.

```
void copyBandwidth(
    String[] class_names
    String[] new_names
)
```

deleteBandwidth(class_names) throws ObjectDoesNotExist, ObjectInUse, LicenseError, DeploymentError

Delete the named bandwidth classes.

```
void deleteBandwidth(
    String[] class_names
)
```

getBandwidthNames() throws LicenseError

Get the names of all the configured bandwidth classes.

```
String[] getBandwidthNames()
```

getMaximum(class_names) throws ObjectDoesNotExist, LicenseError

Get the maximum bandwidth, in kbits/second.

```
Unsigned Integer[] getMaximum(
   String[] class_names
)
```

getMaximumByLocation(location, class_names) throws ObjectDoesNotExist, LicenseError

Get the maximum bandwidth, in kbits/second. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaximumByLocation(
   String location
   String[] class_names
)
```

getNote(class_names) throws ObjectDoesNotExist, LicenseError

Get the note for each of the named Bandwidth classes.

```
String[] getNote(
   String[] class_names
)
```

getSharing(class_names) throws ObjectDoesNotExist, LicenseError

Get the bandwidth sharing mode

```
Catalog.Bandwidth.Sharing[] getSharing(
   String[] class_names
)
```

getSharingByLocation(location, class_names) throws ObjectDoesNotExist, LicenseError

Get the bandwidth sharing mode This is a location specific function, any action will operate on the specified location.

```
Catalog.Bandwidth.Sharing[] getSharingByLocation(
   String location
   String[] class_names
)
```

renameBandwidth(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation, LicenseError

Rename the named bandwidth classes.

```
void renameBandwidth(
   String[] class_names
   String[] new_names
)
```

setMaximum(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the maximum bandwidth, in kbits/second.

```
void setMaximum(
   String[] class_names
   Unsigned Integer[] values
)
```

setMaximumByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the maximum bandwidth, in kbits/second. This is a location specific function, any action will operate on the specified location.

```
void setMaximumByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setNote(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the note for each of the named Bandwidth classes.

```
void setNote(
   String[] class_names
   String[] values
)
```

setSharing(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the bandwidth sharing mode

```
void setSharing(
    String[] class_names
    Catalog.Bandwidth.Sharing[] values
)
```

setSharingByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the bandwidth sharing mode This is a location specific function, any action will operate on the specified location.

```
void setSharingByLocation(
    String location
    String[] class_names
    Catalog.Bandwidth.Sharing[] values
)
```

6.13.2 Enumerations

Catalog.Bandwidth.Sharing

```
enum Catalog.Bandwidth.Sharing {
    # Each connection can use the maximum rate
    connection,

    # Bandwidth is shared per traffic manager
    machine,

    # Bandwidth is shared across all traffic managers
    cluster
}
```

6.14 Catalog.SLM

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/SLM/`

The Catalog.SLM interface allows management of Service Level Monitoring classes. Using this interface, you can create, delete and rename SLM classes, and manage their configuration.

6.14.1 Methods

addSLM(class_names) throws InvalidObjectName, ObjectAlreadyExists, DeploymentError, LicenseError

Add new SLM classes.

```
    void addSLM(
```

```
      String[] class_names
   )
```

copySLM(class_names, new_names) throws ObjectAlreadyExists, InvalidObjectName, ObjectDoesNotExist, DeploymentError, LicenseError

Copy the named SLM classes.

```
   void copySLM(
      String[] class_names
      String[] new_names
   )
```

deleteSLM(class_names) throws ObjectDoesNotExist, ObjectInUse, DeploymentError, LicenseError

Delete the named SLM classes.

```
   void deleteSLM(
      String[] class_names
   )
```

getNote(class_names) throws ObjectDoesNotExist, LicenseError

Get the note for each of the named SLM classes.

```
   String[] getNote(
      String[] class_names
   )
```

getResponseTime(class_names) throws ObjectDoesNotExist, LicenseError

Get the time limit for a response to conform (in milliseconds).

```
   Unsigned Integer[] getResponseTime(
      String[] class_names
   )
```

getResponseTimeByLocation(location, class_names) throws ObjectDoesNotExist, LicenseError

Get the time limit for a response to conform (in milliseconds). This is a location specific function, any action will operate on the specified location.

```
   Unsigned Integer[] getResponseTimeByLocation(
      String location
      String[] class_names
   )
```

getSLMNames() throws LicenseError

Get the names of all the configured SLM classes.

```
String[] getSLMNames()
```

getSeriousThreshold(class_names) throws ObjectDoesNotExist, LicenseError

Get the percentage of conforming responses below which a serious error will be emitted.

```
Unsigned Integer[] getSeriousThreshold(
   String[] class_names
)
```

getSeriousThresholdByLocation(location, class_names) throws ObjectDoesNotExist, LicenseError

Get the percentage of conforming responses below which a serious error will be emitted. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getSeriousThresholdByLocation(
   String location
   String[] class_names
)
```

getWarningThreshold(class_names) throws ObjectDoesNotExist, LicenseError

Get the percentage of conforming responses below which a warning message will be triggered.

```
Unsigned Integer[] getWarningThreshold(
   String[] class_names
)
```

getWarningThresholdByLocation(location, class_names) throws ObjectDoesNotExist, LicenseError

Get the percentage of conforming responses below which a warning message will be triggered. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getWarningThresholdByLocation(
   String location
   String[] class_names
)
```

renameSLM(class_names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, InvalidOperation, DeploymentError, LicenseError

Rename the named SLM classes.

```
void renameSLM(
   String[] class_names
   String[] new_names
)
```

setNote(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the note for each of the named SLM classes.

```
void setNote(
   String[] class_names
   String[] values
)
```

setResponseTime(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the time limit for a response to conform (in milliseconds).

```
void setResponseTime(
   String[] class_names
   Unsigned Integer[] values
)
```

setResponseTimeByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the time limit for a response to conform (in milliseconds). This is a location specific function, any action will operate on the specified location.

```
void setResponseTimeByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setSeriousThreshold(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the percentage of conforming responses below which a serious error will be emitted.

```
void setSeriousThreshold(
   String[] class_names
   Unsigned Integer[] values
)
```

setSeriousThresholdByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the percentage of conforming responses below which a serious error will be emitted. This is a location specific function, any action will operate on the specified location.

```
void setSeriousThresholdByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

setWarningThreshold(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the percentage of conforming responses below which a warning message will be triggered.

```
void setWarningThreshold(
   String[] class_names
   Unsigned Integer[] values
)
```

setWarningThresholdByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the percentage of conforming responses below which a warning message will be triggered. This is a location specific function, any action will operate on the specified location.

```
void setWarningThresholdByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

6.15 Catalog.Rate

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/Rate/`

The Catalog.Rate interface allows management of Rate classes. Using this interface, you can create, delete and rename rate classes, and manage their configuration.

6.15.1 Methods

addRate(class_names) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError

Add new rate classes.

```
void addRate(
    String[] class_names
)
```

copyRate(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Copy the named rate classes.

```
void copyRate(
    String[] class_names
    String[] new_names
)
```

deleteRate(class_names) throws ObjectInUse, ObjectDoesNotExist, DeploymentError

Delete the named rate classes.

```
void deleteRate(
    String[] class_names
)
```

getMaxRatePerMinute(class_names) throws ObjectDoesNotExist

Get the maximum rate at which requests are allowed to be processed, in requests per minute.

```
Unsigned Integer[] getMaxRatePerMinute(
    String[] class_names
)
```

getMaxRatePerMinuteByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum rate at which requests are allowed to be processed, in requests per minute. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxRatePerMinuteByLocation(
    String location
    String[] class_names
)
```

getMaxRatePerSecond(class_names) throws ObjectDoesNotExist

Get the maximum rate at which requests are allowed to be processed, in requests per second.

```
Unsigned Integer[] getMaxRatePerSecond(
   String[] class_names
)
```

getMaxRatePerSecondByLocation(location, class_names) throws ObjectDoesNotExist

Get the maximum rate at which requests are allowed to be processed, in requests per second. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getMaxRatePerSecondByLocation(
   String location
   String[] class_names
)
```

getNote(class_names) throws ObjectDoesNotExist

Get the note for each of the named Rate classes.

```
String[] getNote(
   String[] class_names
)
```

getRateNames()

Get the names of all the configured rate classes.

```
String[] getRateNames()
```

renameRate(class_names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename the named rate classes.

```
void renameRate(
   String[] class_names
   String[] new_names
)
```

setMaxRatePerMinute(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum rate at which requests are allowed to be processed, in requests per minute.

```
void setMaxRatePerMinute(
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxRatePerMinuteByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum rate at which requests are allowed to be processed, in requests per minute. This is a location specific function, any action will operate on the specified location.

```
void setMaxRatePerMinuteByLocation(
    String location
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxRatePerSecond(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum rate at which requests are allowed to be processed, in requests per second.

```
void setMaxRatePerSecond(
    String[] class_names
    Unsigned Integer[] values
)
```

setMaxRatePerSecondByLocation(location, class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the maximum rate at which requests are allowed to be processed, in requests per second. This is a location specific function, any action will operate on the specified location.

```
void setMaxRatePerSecondByLocation(
    String location
    String[] class_names
    Unsigned Integer[] values
)
```

setNote(class_names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError

Set the note for each of the named Rate classes.

```
void setNote(
   String[] class_names
   String[] values
)
```

6.16 Catalog.JavaExtension

URI: `http://soap.zeus.com/zxtm/1.0/Catalog/JavaExtension/`

The Catalog.JavaExtension interface allows management of Java Extensions. Using this interface you can retrieve information on each extension in the system, and set the initialisation properties to alter their behaviour.

6.16.1 Methods

addProperties(class_names, properties) throws LicenseError, ObjectDoesNotExist, InvalidInput

Adds initialisation properties for each of the specified extensions.

```
void addProperties(
   String[] class_names
   Catalog.JavaExtension.Property[][] properties
)
```

deleteJavaExtensionFile(names) throws LicenseError, ObjectDoesNotExist, ObjectInUse

Delete the named Java Extension files.

```
void deleteJavaExtensionFile(
   String[] names
)
```

downloadJavaExtensionFile(name) throws LicenseError, ObjectDoesNotExist

Download the named Java Extension File.

```
Binary Data downloadJavaExtensionFile(
   String name
)
```

editProperties(class_names, properties_being_edited, properties) throws LicenseError, ObjectDoesNotExist, InvalidInput

Edits the initialisation properties for each of the specified extensions.

```
void editProperties(
   String[] class_names
   String[][] properties_being_edited
   Catalog.JavaExtension.Property[][] properties
)
```

getExtensionClassNames() throws LicenseError

Gets the class names of all the extensions currently in the system.

```
String[] getExtensionClassNames()
```

getExtensionErrors(class_names) throws LicenseError, ObjectDoesNotExist

Gets the errors for each of the specified extensions.

```
String[][] getExtensionErrors(
   String[] class_names
)
```

getExtensionInfo(class_names) throws LicenseError, ObjectDoesNotExist

Gets information on each of the specified extensions.

```
Catalog.JavaExtension.Info[] getExtensionInfo(
   String[] class_names
)
```

getJavaExtensionFileNames() throws LicenseError

Get the names of Java Extension files on the traffic manager. This list includes files that contain Java Extension and non-Java Extension files, such as other .jar files.

```
String[] getJavaExtensionFileNames()
```

getProperties(class_names) throws LicenseError, ObjectDoesNotExist

Gets the initialisation properties for each of the specified extensions.

```
Catalog.JavaExtension.Property[][] getProperties(
   String[] class_names
)
```

removeProperties(class_names, prop_names) throws LicenseError, ObjectDoesNotExist, InvalidInput

Removes initialisation properties for each of the specified extensions.

```
void removeProperties(
   String[] class_names
   String[][] prop_names
)
```

uploadJavaExtensionFile(name, content) throws InvalidObjectName, LicenseError, InvalidInput

Uploads a new file that may contain a Java Extension. This will overwrite the file if it already exists.

```
void uploadJavaExtensionFile(
   String name
   Binary Data content
)
```

6.16.2 Structures

Catalog.JavaExtension.Info

This structure contains basic information about a Java Extension in the catalog.

```
struct Catalog.JavaExtension.Info {
   # The Java class name of the extension.
   String class_name;

   # The location of the Java extension class.
   String path;

   # The virtual servers that use this extension.
   String[] virtual_servers;

   # The rules that use this extension.
   String[] rules;
}
```

Catalog.JavaExtension.Property

Represents an initialisation property for an extension.

```
struct Catalog.JavaExtension.Property {
   # The name of this property
   String name;

   # The value of this property
```

```
        String value;
    }
```

6.17 GlobalSettings

URI: `http://soap.zeus.com/zxtm/1.0/GlobalSettings/`

The Global Settings interface allows management of the traffic manager settings.

6.17.1 Methods

addFlipperFrontendCheckAddresses(values) throws InvalidInput, DeploymentError

Add new IP addresses to the list that should be used to check front-end connectivity

```
void addFlipperFrontendCheckAddresses(
   String[] values
)
```

addFlipperFrontendCheckAddressesByLocation(location, values) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Add new IP addresses to the list that should be used to check front-end connectivity This is a location specific function, any action will operate on the specified location.

```
void addFlipperFrontendCheckAddressesByLocation(
   String location
   String[] values
)
```

getASPSessionCacheSize()

Get the maximum number of entries in the ASP session cache.

```
Unsigned Integer getASPSessionCacheSize()
```

getASPSessionCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the ASP session cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getASPSessionCacheSizeByLocation(
   String location
)
```

getAcceptingDelay()

Get how often each traffic manager child process checks whether it should be accepting new connections.

```
Unsigned Integer getAcceptingDelay()
```

getAcceptingDelayByLocation(location) throws ObjectDoesNotExist

Get how often each traffic manager child process checks whether it should be accepting new connections. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getAcceptingDelayByLocation(
    String location
)
```

getAlertEmailInterval()

Get the length of time between alert emails, in seconds. Several alert messages will be stored up and sent in one email.

```
Unsigned Integer getAlertEmailInterval()
```

getAlertEmailIntervalByLocation(location) throws ObjectDoesNotExist

Get the length of time between alert emails, in seconds. Several alert messages will be stored up and sent in one email. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getAlertEmailIntervalByLocation(
    String location
)
```

getAlertEmailMaxAttempts()

Get the number of times to attempt sending an email before giving up.

```
Unsigned Integer getAlertEmailMaxAttempts()
```

getAlertEmailMaxAttemptsByLocation(location) throws ObjectDoesNotExist

Get the number of times to attempt sending an email before giving up. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getAlertEmailMaxAttemptsByLocation(
    String location
)
```

getAutoscalerVerbose()

Get detailed logging of autoscaler status and actions

```
Boolean getAutoscalerVerbose()
```

getAutoscalerVerboseByLocation(location) throws ObjectDoesNotExist

Get detailed logging of autoscaler status and actions This is a location specific function, any action will operate on the specified location.

```
Boolean getAutoscalerVerboseByLocation(
   String location
)
```

getBackendKeepaliveTimeout()

getBackendKeepaliveTimeout is deprecated, please use getIdleConnectionTimeout instead.

```
Unsigned Integer getBackendKeepaliveTimeout()
```

getBackendKeepaliveTimeoutByLocation(location) throws ObjectDoesNotExist

getBackendKeepaliveTimeout is deprecated, please use getIdleConnectionTimeout instead. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getBackendKeepaliveTimeoutByLocation(
   String location
)
```

getBandwidthSharing()

This method is now obsolete and is replaced by Catalog.Bandwidth.getSharing.

```
Boolean getBandwidthSharing()
```

getChunkSize()

Get the default chunk size for reading and writing data, in bytes.

```
Unsigned Integer getChunkSize()
```

getChunkSizeByLocation(location) throws ObjectDoesNotExist

Get the default chunk size for reading and writing data, in bytes. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getChunkSizeByLocation(
```

```
      String location
)
```

getClientFirstOpt()

Get whether client-first network socket optimisations should be used.

```
Boolean getClientFirstOpt()
```

getClientFirstOptByLocation(location) throws ObjectDoesNotExist

Get whether client-first network socket optimisations should be used. This is a location specific function, any action will operate on the specified location.

```
Boolean getClientFirstOptByLocation(
    String location
)
```

getControlAllowHosts()

Get the hosts that are allowed to contact the internal administration port on each traffic manager.

```
String getControlAllowHosts()
```

getControlAllowHostsByLocation(location) throws ObjectDoesNotExist

Get the hosts that are allowed to contact the internal administration port on each traffic manager. This is a location specific function, any action will operate on the specified location.

```
String getControlAllowHostsByLocation(
    String location
)
```

getControlCanUpdateDefault()

Get the value of the control!canupdate key for new cluster members.

```
Boolean getControlCanUpdateDefault()
```

getDNSCacheExpiryTime()

Get the time entries are stored in the DNS cache for, in seconds.

```
Unsigned Integer getDNSCacheExpiryTime()
```

getDNSCacheExpiryTimeByLocation(location) throws ObjectDoesNotExist

Get the time entries are stored in the DNS cache for, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getDNSCacheExpiryTimeByLocation(
    String location
)
```

getDNSCacheNegativeExpiryTime()

Get the time failed lookups are stored in the DNS cache for, in seconds.

```
Unsigned Integer getDNSCacheNegativeExpiryTime()
```

getDNSCacheNegativeExpiryTimeByLocation(location) throws ObjectDoesNotExist

Get the time failed lookups are stored in the DNS cache for, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getDNSCacheNegativeExpiryTimeByLocation(
    String location
)
```

getDNSCacheSize()

Get the maximum number of entries in the DNS cache.

```
Unsigned Integer getDNSCacheSize()
```

getDNSCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the DNS cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getDNSCacheSizeByLocation(
    String location
)
```

getDNSTimeout()

Get the timeout for receiving a response from a DNS Server, in seconds.

```
Unsigned Integer getDNSTimeout()
```

getDNSTimeoutByLocation(location) throws ObjectDoesNotExist

Get the timeout for receiving a response from a DNS Server, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getDNSTimeoutByLocation(
   String location
)
```

getDeadTime()

This method is now obsolete and is replaced by Pool.getNodeFailTime.

```
Unsigned Integer getDeadTime()
```

getEC2AccessKeyID()

Get the Access Key ID used for interacting with the EC2 API.

```
String getEC2AccessKeyID()
```

getEC2AccessKeyIDByLocation(location) throws ObjectDoesNotExist

Get the Access Key ID used for interacting with the EC2 API. This is a location specific function, any action will operate on the specified location.

```
String getEC2AccessKeyIDByLocation(
   String location
)
```

getErrorLevel()

Get the minimum severity of events that should be logged to disk.

```
GlobalSettings.ErrorLevel getErrorLevel()
```

getErrorLevelByLocation(location) throws ObjectDoesNotExist

Get the minimum severity of events that should be logged to disk. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.ErrorLevel getErrorLevelByLocation(
   String location
)
```

getErrorLogFile()

Get the filename that errors are logged to.

```
String getErrorLogFile()
```

getErrorLogFileByLocation(location) throws ObjectDoesNotExist

Get the filename that errors are logged to. This is a location specific function, any action will operate on the specified location.

```
String getErrorLogFileByLocation(
   String location
)
```

getFTPDataBindLow()

Get whether your traffic manager should permit use of FTP data connection source ports lower than 1024. If 'No' your traffic manager can completely drop root privileges, if 'Yes' some or all privileges may be retained in order to bind to low ports.

```
Boolean getFTPDataBindLow()
```

getFTPDataBindLowByLocation(location) throws ObjectDoesNotExist

Get whether your traffic manager should permit use of FTP data connection source ports lower than 1024. If 'No' your traffic manager can completely drop root privileges, if 'Yes' some or all privileges may be retained in order to bind to low ports. This is a location specific function, any action will operate on the specified location.

```
Boolean getFTPDataBindLowByLocation(
   String location
)
```

getFlipperArpCount()

Get the number of ARP packets each traffic manager sends when an interface is raised.

```
Unsigned Integer getFlipperArpCount()
```

getFlipperArpCountByLocation(location) throws ObjectDoesNotExist

Get the number of ARP packets each traffic manager sends when an interface is raised. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getFlipperArpCountByLocation(
   String location
)
```

getFlipperAutofailback()

Get whether Traffic IPs should automatically failback to recovered machines.

```
Boolean getFlipperAutofailback()
```

getFlipperAutofailbackByLocation(location) throws ObjectDoesNotExist

Get whether Traffic IPs should automatically failback to recovered machines. This is a location specific function, any action will operate on the specified location.

```
Boolean getFlipperAutofailbackByLocation(
   String location
)
```

getFlipperFrontendCheckAddresses()

Get the IP addresses that should be used to check front-end connectivity.

```
String[] getFlipperFrontendCheckAddresses()
```

getFlipperFrontendCheckAddressesByLocation(location) throws ObjectDoesNotExist

Get the IP addresses that should be used to check front-end connectivity. This is a location specific function, any action will operate on the specified location.

```
String[] getFlipperFrontendCheckAddressesByLocation(
   String location
)
```

getFlipperHeartbeatMethod()

Get the method used to exchange cluster heartbeat messages.

```
GlobalSettings.FlipperHeartbeatMethod getFlipperHeartbeatMethod()
```

getFlipperHeartbeatMethodByLocation(location) throws ObjectDoesNotExist

Get the method used to exchange cluster heartbeat messages. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.FlipperHeartbeatMethod
getFlipperHeartbeatMethodByLocation(
   String location
)
```

getFlipperMonitorInterval()

Get how frequently (in milliseconds) each traffic manager checks and announces its connectivity.

```
Unsigned Integer getFlipperMonitorInterval()
```

getFlipperMonitorIntervalByLocation(location) throws ObjectDoesNotExist

Get how frequently (in milliseconds) each traffic manager checks and announces its connectivity. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getFlipperMonitorIntervalByLocation(
   String location
)
```

getFlipperMonitorTimeout()

Get how long (in seconds) each traffic manager waits for a response from its connectivity tests or from other traffic managers before registering a failure.

```
Unsigned Integer getFlipperMonitorTimeout()
```

getFlipperMonitorTimeoutByLocation(location) throws ObjectDoesNotExist

Get how long (in seconds) each traffic manager waits for a response from its connectivity tests or from other traffic managers before registering a failure. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getFlipperMonitorTimeoutByLocation(
   String location
)
```

getFlipperMulticastAddress()

Get the multicast address and port used to announce connectivity (e.g. 239.100.1.1:9090).

```
String getFlipperMulticastAddress()
```

getFlipperMulticastAddressByLocation(location) throws ObjectDoesNotExist

Get the multicast address and port used to announce connectivity (e.g. 239.100.1.1:9090). This is a location specific function, any action will operate on the specified location.

```
String getFlipperMulticastAddressByLocation(
   String location
)
```

getFlipperUnicastPort()

Get the unicast UDP port used to announce connectivity (e.g. 9090)

```
Unsigned Integer getFlipperUnicastPort()
```

getFlipperUnicastPortByLocation(location) throws ObjectDoesNotExist

Get the unicast UDP port used to announce connectivity (e.g. 9090) This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getFlipperUnicastPortByLocation(
   String location
)
```

getFlipperUseBindip()

Get whether the heartbeat messages used for fault tolerance are only sent over the management network.

```
Boolean getFlipperUseBindip()
```

getFlipperUseBindipByLocation(location) throws ObjectDoesNotExist

Get whether the heartbeat messages used for fault tolerance are only sent over the management network. This is a location specific function, any action will operate on the specified location.

```
Boolean getFlipperUseBindipByLocation(
   String location
)
```

getFlipperVerbose()

Get whether the traffic manager should logs all the connectivity tests.

```
Boolean getFlipperVerbose()
```

getFlipperVerboseByLocation(location) throws ObjectDoesNotExist

Get whether the traffic manager should logs all the connectivity tests. This is a location specific function, any action will operate on the specified location.

```
Boolean getFlipperVerboseByLocation(
   String location
)
```

getGLBLoadChangeLimit()

Get the maximum change per second to load.

```
Unsigned Integer getGLBLoadChangeLimit()
```

getGLBLoadChangeLimitByLocation(location) throws ObjectDoesNotExist

Get the maximum change per second to load. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getGLBLoadChangeLimitByLocation(
   String location
)
```

getGLBVerbose()

Get whether GSLB should log all DNS queries

```
Boolean getGLBVerbose()
```

getGLBVerboseByLocation(location) throws ObjectDoesNotExist

Get whether GSLB should log all DNS queries This is a location specific function, any action will operate on the specified location.

```
Boolean getGLBVerboseByLocation(
   String location
)
```

getHistoricalTrafficDays()

Get the length of time historical traffic information is kept for, in days (0=keep indefinitely).

```
Unsigned Integer getHistoricalTrafficDays()
```

getHistoricalTrafficDaysByLocation(location) throws ObjectDoesNotExist

Get the length of time historical traffic information is kept for, in days (0=keep indefinitely). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getHistoricalTrafficDaysByLocation(
   String location
)
```

getIPSessionCacheSize()

Get the maximum number of entries in the IP session cache.

```
Unsigned Integer getIPSessionCacheSize()
```

getIPSessionCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the IP session cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getIPSessionCacheSizeByLocation(
   String location
)
```

getIdleConnectionTimeout()

Get how long unused HTTP keepalive connections should be kept before being discarded, in seconds.

```
Unsigned Integer getIdleConnectionTimeout()
```

getIdleConnectionTimeoutByLocation(location) throws ObjectDoesNotExist

Get how long unused HTTP keepalive connections should be kept before being discarded, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getIdleConnectionTimeoutByLocation(
   String location
)
```

getJ2EESessionCacheSize()

Get the maximum number of entries in the J2EE session cache.

```
Unsigned Integer getJ2EESessionCacheSize()
```

getJ2EESessionCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the J2EE session cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getJ2EESessionCacheSizeByLocation(
   String location
)
```

getJavaClasspath()

Get extra Java CLASSPATH settings required for servlets.

```
String getJavaClasspath()
```

getJavaClasspathByLocation(location) throws ObjectDoesNotExist

Get extra Java CLASSPATH settings required for servlets. This is a location specific function, any action will operate on the specified location.

```
String getJavaClasspathByLocation(
   String location
)
```

getJavaCommand()

Get the command (and arguments) used to start Java.

```
String getJavaCommand()
```

getJavaCommandByLocation(location) throws ObjectDoesNotExist

Get the command (and arguments) used to start Java. This is a location specific function, any action will operate on the specified location.

```
String getJavaCommandByLocation(
   String location
)
```

getJavaEnabled()

Get whether to enable Java support.

```
Boolean getJavaEnabled()
```

getJavaEnabledByLocation(location) throws ObjectDoesNotExist

Get whether to enable Java support. This is a location specific function, any action will operate on the specified location.

```
Boolean getJavaEnabledByLocation(
   String location
)
```

getJavaLib()

Get the location of the java library directory

```
String getJavaLib()
```

getJavaLibByLocation(location) throws ObjectDoesNotExist

Get the location of the java library directory This is a location specific function, any action will operate on the specified location.

```
String getJavaLibByLocation(
    String location
)
```

getJavaMaxConns()

Get the maximum number of Java threads

```
Unsigned Integer getJavaMaxConns()
```

getJavaMaxConnsByLocation(location) throws ObjectDoesNotExist

Get the maximum number of Java threads This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getJavaMaxConnsByLocation(
    String location
)
```

getJavaSessionAge()

Get the default maximum age of Java session persistence

```
Unsigned Integer getJavaSessionAge()
```

getJavaSessionAgeByLocation(location) throws ObjectDoesNotExist

Get the default maximum age of Java session persistence This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getJavaSessionAgeByLocation(
    String location
)
```

getListenQueueSize()

Get the size of the listen queue for managing incoming connections.

```
Unsigned Integer getListenQueueSize()
```

getListenQueueSizeByLocation(location) throws ObjectDoesNotExist

Get the size of the listen queue for managing incoming connections. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getListenQueueSizeByLocation(
    String location
)
```

getLogFlushFlushTime()

Get the length of time to wait before flushing the request log files for each virtual server, in seconds.

```
Unsigned Integer getLogFlushFlushTime()
```

getLogFlushFlushTimeByLocation(location) throws ObjectDoesNotExist

Get the length of time to wait before flushing the request log files for each virtual server, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getLogFlushFlushTimeByLocation(
    String location
)
```

getLogInterval()

Get the length of time between log messages for log intensive features e.g. SLM, in seconds.

```
Unsigned Integer getLogInterval()
```

getLogIntervalByLocation(location) throws ObjectDoesNotExist

Get the length of time between log messages for log intensive features e.g. SLM, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getLogIntervalByLocation(
    String location
)
```

getLogRate()

Get is the maximum number of connection errors logged per second.

```
Unsigned Integer getLogRate()
```

getLogRateByLocation(location) throws ObjectDoesNotExist

Get is the maximum number of connection errors logged per second. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getLogRateByLocation(
   String location
)
```

getLogReopenTime()

Get the length of time to wait before re-opening request log files, to handle log file rotation, in seconds.

```
Unsigned Integer getLogReopenTime()
```

getLogReopenTimeByLocation(location) throws ObjectDoesNotExist

Get the length of time to wait before re-opening request log files, to handle log file rotation, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getLogReopenTimeByLocation(
   String location
)
```

getLoginBanner()

Get the banner to be shown on the login page and by appliance SSH servers.

```
String getLoginBanner()
```

getMaxAccepting()

Get how many traffic manager child processes accept new connections.

```
Unsigned Integer getMaxAccepting()
```

getMaxAcceptingByLocation(location) throws ObjectDoesNotExist

Get how many traffic manager child processes accept new connections. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getMaxAcceptingByLocation(
   String location
)
```

getMaxIdleConnections()

Get the maximum number of unused HTTP keepalive connections to all nodes that should maintained for re-use.

```
Unsigned Integer getMaxIdleConnections()
```

getMaxIdleConnectionsByLocation(location) throws ObjectDoesNotExist

Get the maximum number of unused HTTP keepalive connections to all nodes that should maintained for re-use. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getMaxIdleConnectionsByLocation(
   String location
)
```

getMaxKeepalives()

getMaxKeepalives is deprecated, please use getMaxIdleConnections instead.

```
Unsigned Integer getMaxKeepalives()
```

getMaxKeepalivesByLocation(location) throws ObjectDoesNotExist

getMaxKeepalives is deprecated, please use getMaxIdleConnections instead. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getMaxKeepalivesByLocation(
   String location
)
```

getMaxRetries()

This method is now obsolete and is replaced by Pool.getNodeConnectionAttempts.

```
Unsigned Integer getMaxRetries()
```

getMaximumFDCount()

Get the maximum number of file descriptors that your traffic manager will allocate

```
Unsigned Integer getMaximumFDCount()
```

getMaximumFDCountByLocation(location) throws ObjectDoesNotExist

Get the maximum number of file descriptors that your traffic manager will allocate This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getMaximumFDCountByLocation(
   String location
)
```

getMonitorNumNodes()

Get the maximum number of nodes that can be monitored.

```
Unsigned Integer getMonitorNumNodes()
```

getMonitorNumNodesByLocation(location) throws ObjectDoesNotExist

Get the maximum number of nodes that can be monitored. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getMonitorNumNodesByLocation(
   String location
)
```

getMultipleAccept()

Get whether your traffic manager should try and read multiple new connections each time a new client connects.

```
Boolean getMultipleAccept()
```

getMultipleAcceptByLocation(location) throws ObjectDoesNotExist

Get whether your traffic manager should try and read multiple new connections each time a new client connects. This is a location specific function, any action will operate on the specified location.

```
Boolean getMultipleAcceptByLocation(
   String location
)
```

getNodeConnectionAttempts()

This method is now obsolete and is replaced by Pool.getNodeConnectionAttempts.

```
Unsigned Integer getNodeConnectionAttempts()
```

getNodeFailTime()

This method is now obsolete and is replaced by Pool.getNodeFailTime.

```
Unsigned Integer getNodeFailTime()
```

getRateClassLimit()

Get the maximum number of Rate classes allowed.

```
Unsigned Integer getRateClassLimit()
```

getRateClassLimitByLocation(location) throws ObjectDoesNotExist

Get the maximum number of Rate classes allowed. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getRateClassLimitByLocation(
   String location
)
```

getRecentConns()

Get the details of how many recently closed connections each traffic manager process should save for use with the Connections page.

```
Unsigned Integer getRecentConns()
```

getRecentConnsByLocation(location) throws ObjectDoesNotExist

Get the details of how many recently closed connections each traffic manager process should save for use with the Connections page. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getRecentConnsByLocation(
   String location
)
```

getRecentConnsRetainTime()

Get for how long a snapshot should be retained on the Connections page.

```
Unsigned Integer getRecentConnsRetainTime()
```

getRecentConnsRetainTimeByLocation(location) throws ObjectDoesNotExist

Get for how long a snapshot should be retained on the Connections page. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getRecentConnsRetainTimeByLocation(
   String location
)
```

getRecentConnsSnapshotSize()

Get the maximum number of connections each traffic manager process should show for a snapshot on the Connections page.

```
Unsigned Integer getRecentConnsSnapshotSize()
```

getRecentConnsSnapshotSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of connections each traffic manager process should show for a snapshot on the Connections page. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getRecentConnsSnapshotSizeByLocation(
    String location
)
```

getSLMClassLimit()

Get the maximum number of SLM classes allowed.

```
Unsigned Integer getSLMClassLimit()
```

getSLMClassLimitByLocation(location) throws ObjectDoesNotExist

Get the maximum number of SLM classes allowed. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSLMClassLimitByLocation(
    String location
)
```

getSNMPUserCounters()

Get the number of user defined SNMP counters.

```
Unsigned Integer getSNMPUserCounters()
```

getSNMPUserCountersByLocation(location) throws ObjectDoesNotExist

Get the number of user defined SNMP counters. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSNMPUserCountersByLocation(
    String location
)
```

getSSL3AllowRehandshake()

Get whether SSL / TLS re-handshakes are supported.

```
GlobalSettings.SSL3AllowRehandshake getSSL3AllowRehandshake()
```

getSSL3AllowRehandshakeByLocation(location) throws ObjectDoesNotExist

Get whether SSL / TLS re-handshakes are supported. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.SSL3AllowRehandshake getSSL3AllowRehandshakeByLocation(
    String location
)
```

getSSL3Ciphers()

Get the list of configured SSL ciphers (available ciphers can be displayed using the command $ZEUSHOME/zxtm/bin/zeus.zxtm -s).

```
String getSSL3Ciphers()
```

getSSL3CiphersByLocation(location) throws ObjectDoesNotExist

Get the list of configured SSL ciphers (available ciphers can be displayed using the command $ZEUSHOME/zxtm/bin/zeus.zxtm -s). This is a location specific function, any action will operate on the specified location.

```
String getSSL3CiphersByLocation(
    String location
)
```

getSSLDFailureCount()

getSSLDFailureCount is deprecated, please use getSSLHardwareFailureCount instead.

```
Unsigned Integer getSSLDFailureCount()
```

getSSLDFailureCountByLocation(location) throws ObjectDoesNotExist

getSSLDFailureCount is deprecated, please use getSSLHardwareFailureCount instead. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSSLDFailureCountByLocation(
    String location
)
```

getSSLDPKCS11Lib()

getSSLDPKCS11Lib is deprecated, please use getSSLHardwarePKCS11Lib instead.

```
String getSSLDPKCS11Lib()
```

getSSLDPKCS11LibByLocation(location) throws ObjectDoesNotExist

getSSLDPKCS11Lib is deprecated, please use getSSLHardwarePKCS11Lib instead. This is a location specific function, any action will operate on the specified location.

```
String getSSLDPKCS11LibByLocation(
    String location
)
```

getSSLHardwareAccelerator()

Get whether your traffic manager should always attempt to use SSL hardware.

```
Boolean getSSLHardwareAccelerator()
```

getSSLHardwareAcceleratorByLocation(location) throws ObjectDoesNotExist

Get whether your traffic manager should always attempt to use SSL hardware. This is a location specific function, any action will operate on the specified location.

```
Boolean getSSLHardwareAcceleratorByLocation(
    String location
)
```

getSSLHardwareFailureCount()

Get the number of consecutive failures from the SSL hardware that will be tolerated before your traffic manager tries to log in again.

```
Unsigned Integer getSSLHardwareFailureCount()
```

getSSLHardwareFailureCountByLocation(location) throws ObjectDoesNotExist

Get the number of consecutive failures from the SSL hardware that will be tolerated before your traffic manager tries to log in again. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSSLHardwareFailureCountByLocation(
    String location
)
```

getSSLHardwarePKCS11Lib()

Get the location of the PKCS#11 library supplied by your hardware vendor.

```
String getSSLHardwarePKCS11Lib()
```

getSSLHardwarePKCS11LibByLocation(location) throws ObjectDoesNotExist

Get the location of the PKCS#11 library supplied by your hardware vendor. This is a location specific function, any action will operate on the specified location.

```
String getSSLHardwarePKCS11LibByLocation(
   String location
)
```

getSSLHardwareType()

Get the device driver library name.

```
GlobalSettings.SSLHardwareType getSSLHardwareType()
```

getSSLHardwareTypeByLocation(location) throws ObjectDoesNotExist

Get the device driver library name. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.SSLHardwareType getSSLHardwareTypeByLocation(
   String location
)
```

getSSLSessionCacheSize()

Get the maximum number of entries in the SSL session cache. This is used to provide persistence based on SSL session IDs.

```
Unsigned Integer getSSLSessionCacheSize()
```

getSSLSessionCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the SSL session cache. This is used to provide persistence based on SSL session IDs. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSSLSessionCacheSizeByLocation(
   String location
)
```

getSSLSessionIDCacheExpiryTime()

Get the length of time that SSL session IDs are stored, in seconds.

```
Unsigned Integer getSSLSessionIDCacheExpiryTime()
```

getSSLSessionIDCacheExpiryTimeByLocation(location) throws ObjectDoesNotExist

Get the length of time that SSL session IDs are stored, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSSLSessionIDCacheExpiryTimeByLocation(
    String location
)
```

getSSLSessionIDCacheSize()

Get the number of entries in the SSL session ID cache.

```
Unsigned Integer getSSLSessionIDCacheSize()
```

getSSLSessionIDCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the number of entries in the SSL session ID cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSSLSessionIDCacheSizeByLocation(
    String location
)
```

getSSLSupportSSL2()

Get whether SSLv2 support is enabled.

```
Boolean getSSLSupportSSL2()
```

getSSLSupportSSL2ByLocation(location) throws ObjectDoesNotExist

Get whether SSLv2 support is enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean getSSLSupportSSL2ByLocation(
    String location
)
```

getSSLSupportSSL3()

Get whether SSLv3 support is enabled.

```
Boolean getSSLSupportSSL3()
```

getSSLSupportSSL3ByLocation(location) throws ObjectDoesNotExist

Get whether SSLv3 support is enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean getSSLSupportSSL3ByLocation(
   String location
)
```

getSSLSupportTLS1()

Get whether TLSv1 support is enabled.

```
Boolean getSSLSupportTLS1()
```

getSSLSupportTLS11()

Get whether TLSv1.1 support is enabled.

```
Boolean getSSLSupportTLS11()
```

getSSLSupportTLS11ByLocation(location) throws ObjectDoesNotExist

Get whether TLSv1.1 support is enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean getSSLSupportTLS11ByLocation(
   String location
)
```

getSSLSupportTLS1ByLocation(location) throws ObjectDoesNotExist

Get whether TLSv1 support is enabled. This is a location specific function, any action will operate on the specified location.

```
Boolean getSSLSupportTLS1ByLocation(
   String location
)
```

getSharedPoolSize()

Get is the size of shared memory pool to be used for shared storage across worker processes.

```
String getSharedPoolSize()
```

getSharedPoolSizeByLocation(location) throws ObjectDoesNotExist

Get is the size of shared memory pool to be used for shared storage across worker processes. This is a location specific function, any action will operate on the specified location.

```
String getSharedPoolSizeByLocation(
    String location
)
```

getSoapIdleMinutes()

Get the number of minutes the SOAP server remain idle before exiting

```
Unsigned Integer getSoapIdleMinutes()
```

getSoapIdleMinutesByLocation(location) throws ObjectDoesNotExist

Get the number of minutes the SOAP server remain idle before exiting This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSoapIdleMinutesByLocation(
    String location
)
```

getSocketOptimizations()

Get whether potential network socket optimisations should be used.

```
GlobalSettings.SocketOptimizations getSocketOptimizations()
```

getSocketOptimizationsByLocation(location) throws ObjectDoesNotExist

Get whether potential network socket optimisations should be used. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.SocketOptimizations getSocketOptimizationsByLocation(
    String location
)
```

getSsldAccel()

getSsldAccel is deprecated, please use getSSLHardwareAccelerator instead.

```
Boolean getSsldAccel()
```

getSsldAccelByLocation(location) throws ObjectDoesNotExist

getSsldAccel is deprecated, please use getSSLHardwareAccelerator instead. This is a location specific function, any action will operate on the specified location.

```
Boolean getSsldAccelByLocation(
   String location
)
```

getSsldLibrary()

getSsldLibrary is deprecated, please use getSSLHardwareType instead.

```
GlobalSettings.SsldLibrary getSsldLibrary()
```

getSsldLibraryByLocation(location) throws ObjectDoesNotExist

getSsldLibrary is deprecated, please use getSSLHardwareType instead. This is a location specific function, any action will operate on the specified location.

```
GlobalSettings.SsldLibrary getSsldLibraryByLocation(
   String location
)
```

getStateSyncTime()

Get how often the cache state is propagated to other traffic managers in the cluster, in seconds.

```
Unsigned Integer getStateSyncTime()
```

getStateSyncTimeByLocation(location) throws ObjectDoesNotExist

Get how often the cache state is propagated to other traffic managers in the cluster, in seconds. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getStateSyncTimeByLocation(
   String location
)
```

getStateSyncTimeout()

Get the timeout for state propagation between cluster members, in seconds

```
Unsigned Integer getStateSyncTimeout()
```

getStateSyncTimeoutByLocation(location) throws ObjectDoesNotExist

Get the timeout for state propagation between cluster members, in seconds This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getStateSyncTimeoutByLocation(
    String location
)
```

getSystemReadBufferSize()

Get the size of the operating system's read buffer, in bytes (0 means use the system default).

```
Unsigned Integer getSystemReadBufferSize()
```

getSystemReadBufferSizeByLocation(location) throws ObjectDoesNotExist

Get the size of the operating system's read buffer, in bytes (0 means use the system default). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSystemReadBufferSizeByLocation(
    String location
)
```

getSystemWriteBufferSize()

Get the size of the operating system's write buffer, in bytes (0 means use the system default).

```
Unsigned Integer getSystemWriteBufferSize()
```

getSystemWriteBufferSizeByLocation(location) throws ObjectDoesNotExist

Get the size of the operating system's write buffer, in bytes (0 means use the system default). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getSystemWriteBufferSizeByLocation(
    String location
)
```

getTrafficIPGroupLimit()

Get the maximum number of Traffic IP Groups allowed.

```
Unsigned Integer getTrafficIPGroupLimit()
```

getTrafficIPGroupLimitByLocation(location) throws ObjectDoesNotExist

Get the maximum number of Traffic IP Groups allowed. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getTrafficIPGroupLimitByLocation(
    String location
)
```

getTrafficScriptMemoryWarning()

Get the amount of buffered network data a TrafficScript rule can buffer before a warning is logged, in bytes.

```
Unsigned Integer getTrafficScriptMemoryWarning()
```

getTrafficScriptMemoryWarningByLocation(location) throws ObjectDoesNotExist

Get the amount of buffered network data a TrafficScript rule can buffer before a warning is logged, in bytes. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getTrafficScriptMemoryWarningByLocation(
    String location
)
```

getTrafficscriptArrayElements()

Get the number of array elements that can be stored before additional memory is allocated.

```
Unsigned Integer getTrafficscriptArrayElements()
```

getTrafficscriptArrayElementsByLocation(location) throws ObjectDoesNotExist

Get the number of array elements that can be stored before additional memory is allocated. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getTrafficscriptArrayElementsByLocation(
    String location
)
```

getTrafficscriptDataSize()

Get the maximum size of the TrafficScript shared data pool (specified as a percentage of system RAM, e.g. '5%', or an absolute size, e.g. 200MB)

```
String getTrafficscriptDataSize()
```

getTrafficscriptDataSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum size of the TrafficScript shared data pool (specified as a percentage of system RAM, e.g. '5%', or an absolute size, e.g. 200MB) This is a location specific function, any action will operate on the specified location.

```
String getTrafficscriptDataSizeByLocation(
    String location
)
```

getTrafficscriptMaxInstr()

Get the maximum number of instructions a TrafficScript rule will run before being aborted.

```
Unsigned Integer getTrafficscriptMaxInstr()
```

getTrafficscriptMaxInstrByLocation(location) throws ObjectDoesNotExist

Get the maximum number of instructions a TrafficScript rule will run before being aborted. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getTrafficscriptMaxInstrByLocation(
    String location
)
```

getTrafficscriptRegexCacheSize()

Get the number of regular expressions to cache

```
Unsigned Integer getTrafficscriptRegexCacheSize()
```

getTrafficscriptRegexCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the number of regular expressions to cache This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getTrafficscriptRegexCacheSizeByLocation(
    String location
)
```

getTrafficscriptVariablePoolUse()

Get whether the 'pool.use' and 'pool.select' TrafficScript functions accept variables as well as literal strings.

```
Boolean getTrafficscriptVariablePoolUse()
```

getTrafficscriptVariablePoolUseByLocation(location) throws ObjectDoesNotExist

Get whether the 'pool.use' and 'pool.select' TrafficScript functions accept variables as well as literal strings. This is a location specific function, any action will operate on the specified location.

```
Boolean getTrafficscriptVariablePoolUseByLocation(
    String location
)
```

getUniversalSessionCacheSize()

Get the maximum number of entries in the universal session cache.

```
Unsigned Integer getUniversalSessionCacheSize()
```

getUniversalSessionCacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum number of entries in the universal session cache. This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getUniversalSessionCacheSizeByLocation(
    String location
)
```

getWebcacheDisk()

Get whether the webcache is stored on disk

```
Boolean getWebcacheDisk()
```

getWebcacheDiskByLocation(location) throws ObjectDoesNotExist

Get whether the webcache is stored on disk This is a location specific function, any action will operate on the specified location.

```
Boolean getWebcacheDiskByLocation(
    String location
)
```

getWebcacheDiskDir()

Get the disk cache location

```
String getWebcacheDiskDir()
```

getWebcacheDiskDirByLocation(location) throws ObjectDoesNotExist

Get the disk cache location This is a location specific function, any action will operate on the specified location.

```
String getWebcacheDiskDirByLocation(
    String location
)
```

getWebcacheMaxFileNum()

Get the maximum number of files that can be stored in the web cache

```
Unsigned Integer getWebcacheMaxFileNum()
```

getWebcacheMaxFileNumByLocation(location) throws ObjectDoesNotExist

Get the maximum number of files that can be stored in the web cache This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer getWebcacheMaxFileNumByLocation(
    String location
)
```

getWebcacheMaxFileSize()

Get the largest size of a cacheable object, relative to the total cache size, e.g. '2%', or as an absolute size in kB (default), MB or GB, e.g. '20MB'.

```
String getWebcacheMaxFileSize()
```

getWebcacheMaxFileSizeByLocation(location) throws ObjectDoesNotExist

Get the largest size of a cacheable object, relative to the total cache size, e.g. '2%', or as an absolute size in kB (default), MB or GB, e.g. '20MB'. This is a location specific function, any action will operate on the specified location.

```
String getWebcacheMaxFileSizeByLocation(
    String location
)
```

getWebcacheNormalizeQuery()

Get whether the assignment sub-strings in the parameter string are put into alphabetical order.

```
Boolean getWebcacheNormalizeQuery()
```

getWebcacheNormalizeQueryByLocation(location) throws ObjectDoesNotExist

Get whether the assignment sub-strings in the parameter string are put into alphabetical order. This is a location specific function, any action will operate on the specified location.

```
Boolean getWebcacheNormalizeQueryByLocation(
    String location
)
```

getWebcacheSize()

Get the maximum size of the HTTP web page cache, (specified as a percentage of system RAM, e.g. '20%', or an absolute size, e.g. 200MB)

```
String getWebcacheSize()
```

getWebcacheSizeByLocation(location) throws ObjectDoesNotExist

Get the maximum size of the HTTP web page cache, (specified as a percentage of system RAM, e.g. '20%', or an absolute size, e.g. 200MB) This is a location specific function, any action will operate on the specified location.

```
String getWebcacheSizeByLocation(
    String location
)
```

getWebcacheVerbose()

Get whether an X-Cache-Info header to show cacheability should be added.

```
Boolean getWebcacheVerbose()
```

getWebcacheVerboseByLocation(location) throws ObjectDoesNotExist

Get whether an X-Cache-Info header to show cacheability should be added. This is a location specific function, any action will operate on the specified location.

```
Boolean getWebcacheVerboseByLocation(
    String location
)
```

removeFlipperFrontendCheckAddresses(values) throws InvalidInput, DeploymentError

Remove IP addresses from the list that should be used to check front-end connectivity

```
void removeFlipperFrontendCheckAddresses(
   String[] values
)
```

removeFlipperFrontendCheckAddressesByLocation(location, values) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Remove IP addresses from the list that should be used to check front-end connectivity This is a location specific function, any action will operate on the specified location.

```
void removeFlipperFrontendCheckAddressesByLocation(
   String location
   String[] values
)
```

setASPSessionCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the ASP session cache.

```
void setASPSessionCacheSize(
   Unsigned Integer value
)
```

setASPSessionCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the ASP session cache. This is a location specific function, any action will operate on the specified location.

```
void setASPSessionCacheSizeByLocation(
   String location
   Unsigned Integer value
)
```

setAcceptingDelay(value) throws InvalidInput, DeploymentError

Set how often each traffic manager child process checks whether it should be accepting new connections.

```
void setAcceptingDelay(
   Unsigned Integer value
)
```

setAcceptingDelayByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how often each traffic manager child process checks whether it should be accepting new connections. This is a location specific function, any action will operate on the specified location.

```
void setAcceptingDelayByLocation(
   String location
   Unsigned Integer value
)
```

setAlertEmailInterval(value) throws InvalidInput, DeploymentError

Set the length of time between alert emails, in seconds. Several alert messages will be stored up and sent in one email.

```
void setAlertEmailInterval(
   Unsigned Integer value
)
```

setAlertEmailIntervalByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time between alert emails, in seconds. Several alert messages will be stored up and sent in one email. This is a location specific function, any action will operate on the specified location.

```
void setAlertEmailIntervalByLocation(
   String location
   Unsigned Integer value
)
```

setAlertEmailMaxAttempts(value) throws InvalidInput, DeploymentError

Set the number of times to attempt sending an email before giving up.

```
void setAlertEmailMaxAttempts(
   Unsigned Integer value
)
```

setAlertEmailMaxAttemptsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of times to attempt sending an email before giving up. This is a location specific function, any action will operate on the specified location.

```
void setAlertEmailMaxAttemptsByLocation(
   String location
```

```
    Unsigned Integer value
)
```

setAutoscalerVerbose(value) throws InvalidInput, DeploymentError

Set detailed logging of autoscaler status and actions

```
void setAutoscalerVerbose(
    Boolean value
)
```

setAutoscalerVerboseByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set detailed logging of autoscaler status and actions This is a location specific function, any action will operate on the specified location.

```
void setAutoscalerVerboseByLocation(
    String location
    Boolean value
)
```

setBackendKeepaliveTimeout(value) throws InvalidInput, DeploymentError

setBackendKeepaliveTimeout is deprecated, please use setIdleConnectionTimeout instead.

```
void setBackendKeepaliveTimeout(
    Unsigned Integer value
)
```

setBackendKeepaliveTimeoutByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setBackendKeepaliveTimeout is deprecated, please use setIdleConnectionTimeout instead. This is a location specific function, any action will operate on the specified location.

```
void setBackendKeepaliveTimeoutByLocation(
    String location
    Unsigned Integer value
)
```

setBandwidthSharing(value) throws InvalidInput, DeploymentError

This method is now obsolete and is replaced by Catalog.Bandwidth.setSharing.

```
void setBandwidthSharing(
    Boolean value
)
```

setChunkSize(value) throws InvalidInput, DeploymentError

Set the default chunk size for reading and writing data, in bytes.

```
void setChunkSize(
    Unsigned Integer value
)
```

setChunkSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the default chunk size for reading and writing data, in bytes. This is a location specific function, any action will operate on the specified location.

```
void setChunkSizeByLocation(
    String location
    Unsigned Integer value
)
```

setClientFirstOpt(value) throws InvalidInput, DeploymentError

Set whether client-first network socket optimisations should be used.

```
void setClientFirstOpt(
    Boolean value
)
```

setClientFirstOptByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether client-first network socket optimisations should be used. This is a location specific function, any action will operate on the specified location.

```
void setClientFirstOptByLocation(
    String location
    Boolean value
)
```

setControlAllowHosts(value) throws InvalidInput, DeploymentError

Set the hosts that are allowed to contact the internal administration port on each traffic manager.

```
void setControlAllowHosts(
    String value
)
```

setControlAllowHostsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the hosts that are allowed to contact the internal administration port on each traffic manager. This is a location specific function, any action will operate on the specified location.

```
void setControlAllowHostsByLocation(
   String location
   String value
)
```

setControlCanUpdateDefault(value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the value of the control!canupdate key for new cluster members.

```
void setControlCanUpdateDefault(
   Boolean value
)
```

setDNSCacheExpiryTime(value) throws InvalidInput, DeploymentError

Set the time entries are stored in the DNS cache for, in seconds.

```
void setDNSCacheExpiryTime(
   Unsigned Integer value
)
```

setDNSCacheExpiryTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the time entries are stored in the DNS cache for, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setDNSCacheExpiryTimeByLocation(
   String location
   Unsigned Integer value
)
```

setDNSCacheNegativeExpiryTime(value) throws InvalidInput, DeploymentError

Set the time failed lookups are stored in the DNS cache for, in seconds.

```
void setDNSCacheNegativeExpiryTime(
   Unsigned Integer value
)
```

setDNSCacheNegativeExpiryTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the time failed lookups are stored in the DNS cache for, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setDNSCacheNegativeExpiryTimeByLocation(
   String location
   Unsigned Integer value
)
```

setDNSCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the DNS cache.

```
void setDNSCacheSize(
   Unsigned Integer value
)
```

setDNSCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the DNS cache. This is a location specific function, any action will operate on the specified location.

```
void setDNSCacheSizeByLocation(
   String location
   Unsigned Integer value
)
```

setDNSTimeout(value) throws InvalidInput, DeploymentError

Set the timeout for receiving a response from a DNS Server, in seconds.

```
void setDNSTimeout(
   Unsigned Integer value
)
```

setDNSTimeoutByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the timeout for receiving a response from a DNS Server, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setDNSTimeoutByLocation(
   String location
   Unsigned Integer value
)
```

setDeadTime(value) throws InvalidInput, DeploymentError

This method is now obsolete and is replaced by Pool.setNodeFailTime.

```
void setDeadTime(
   Unsigned Integer value
)
```

setEC2AccessKeyID(value) throws InvalidInput, DeploymentError

Set the Access Key ID used for interacting with the EC2 API.

```
void setEC2AccessKeyID(
   String value
)
```

setEC2AccessKeyIDByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the Access Key ID used for interacting with the EC2 API. This is a location specific function, any action will operate on the specified location.

```
void setEC2AccessKeyIDByLocation(
   String location
   String value
)
```

setEC2SecretAccessKey(value) throws InvalidInput, DeploymentError

Set the Secret Access Key used for interacting with the EC2 API.

```
void setEC2SecretAccessKey(
   String value
)
```

setEC2SecretAccessKeyByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the Secret Access Key used for interacting with the EC2 API. This is a location specific function, any action will operate on the specified location.

```
void setEC2SecretAccessKeyByLocation(
   String location
   String value
)
```

setErrorLevel(value) throws InvalidInput, DeploymentError

Set the minimum severity of events that should be logged to disk.

```
void setErrorLevel(
    GlobalSettings.ErrorLevel value
)
```

setErrorLevelByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the minimum severity of events that should be logged to disk. This is a location specific function, any action will operate on the specified location.

```
void setErrorLevelByLocation(
    String location
    GlobalSettings.ErrorLevel value
)
```

setErrorLogFile(value) throws InvalidInput, DeploymentError

Set the filename that errors are logged to.

```
void setErrorLogFile(
    String value
)
```

setErrorLogFileByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the filename that errors are logged to. This is a location specific function, any action will operate on the specified location.

```
void setErrorLogFileByLocation(
    String location
    String value
)
```

setFTPDataBindLow(value) throws InvalidInput, DeploymentError

Set whether your traffic manager should permit use of FTP data connection source ports lower than 1024. If 'No' your traffic manager can completely drop root privileges, if 'Yes' some or all privileges may be retained in order to bind to low ports.

```
void setFTPDataBindLow(
    Boolean value
)
```

setFTPDataBindLowByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether your traffic manager should permit use of FTP data connection source ports lower than 1024. If 'No' your traffic manager can completely drop root privileges, if 'Yes' some or all privileges may be retained in order to bind to low ports. This is a location specific function, any action will operate on the specified location.

```
void setFTPDataBindLowByLocation(
   String location
   Boolean value
)
```

setFlipperArpCount(value) throws InvalidInput, DeploymentError

Set the number of ARP packets each traffic manager sends when an interface is raised.

```
void setFlipperArpCount(
   Unsigned Integer value
)
```

setFlipperArpCountByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of ARP packets each traffic manager sends when an interface is raised. This is a location specific function, any action will operate on the specified location.

```
void setFlipperArpCountByLocation(
   String location
   Unsigned Integer value
)
```

setFlipperAutofailback(value) throws InvalidInput, DeploymentError

Set whether Traffic IPs should automatically failback to recovered machines.

```
void setFlipperAutofailback(
   Boolean value
)
```

setFlipperAutofailbackByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether Traffic IPs should automatically failback to recovered machines. This is a location specific function, any action will operate on the specified location.

```
void setFlipperAutofailbackByLocation(
   String location
   Boolean value
```

```
)
```

setFlipperFrontendCheckAddresses(values) throws InvalidInput, DeploymentError

Set the IP addresses that should be used to check front-end connectivity.

```
void setFlipperFrontendCheckAddresses(
   String[] values
)
```

setFlipperFrontendCheckAddressesByLocation(location, values) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the IP addresses that should be used to check front-end connectivity. This is a location specific function, any action will operate on the specified location.

```
void setFlipperFrontendCheckAddressesByLocation(
   String location
   String[] values
)
```

setFlipperHeartbeatMethod(value) throws InvalidInput, DeploymentError

Set the method used to exchange cluster heartbeat messages.

```
void setFlipperHeartbeatMethod(
   GlobalSettings.FlipperHeartbeatMethod value
)
```

setFlipperHeartbeatMethodByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the method used to exchange cluster heartbeat messages. This is a location specific function, any action will operate on the specified location.

```
void setFlipperHeartbeatMethodByLocation(
   String location
   GlobalSettings.FlipperHeartbeatMethod value
)
```

setFlipperMonitorInterval(value) throws InvalidInput, DeploymentError

Set how frequently (in milliseconds) each traffic manager checks and announces its connectivity.

```
void setFlipperMonitorInterval(
   Unsigned Integer value
```

)

setFlipperMonitorIntervalByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how frequently (in milliseconds) each traffic manager checks and announces its connectivity. This is a location specific function, any action will operate on the specified location.

```
void setFlipperMonitorIntervalByLocation(
   String location
   Unsigned Integer value
)
```

setFlipperMonitorTimeout(value) throws InvalidInput, DeploymentError

Set how long (in seconds) each traffic manager waits for a response from its connectivity tests or from other traffic managers before registering a failure.

```
void setFlipperMonitorTimeout(
   Unsigned Integer value
)
```

setFlipperMonitorTimeoutByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how long (in seconds) each traffic manager waits for a response from its connectivity tests or from other traffic managers before registering a failure. This is a location specific function, any action will operate on the specified location.

```
void setFlipperMonitorTimeoutByLocation(
   String location
   Unsigned Integer value
)
```

setFlipperMulticastAddress(value) throws InvalidInput, DeploymentError

Set the multicast address and port used to announce connectivity (e.g. 239.100.1.1:9090).

```
void setFlipperMulticastAddress(
   String value
)
```

setFlipperMulticastAddressByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the multicast address and port used to announce connectivity (e.g. 239.100.1.1:9090). This is a location specific function, any action will operate on the specified location.

```
void setFlipperMulticastAddressByLocation(
   String location
   String value
)
```

setFlipperUnicastPort(value) throws InvalidInput, DeploymentError

Set the unicast UDP port used to announce connectivity (e.g. 9090)

```
void setFlipperUnicastPort(
   Unsigned Integer value
)
```

setFlipperUnicastPortByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the unicast UDP port used to announce connectivity (e.g. 9090) This is a location specific function, any action will operate on the specified location.

```
void setFlipperUnicastPortByLocation(
   String location
   Unsigned Integer value
)
```

setFlipperUseBindip(value) throws InvalidInput, DeploymentError

Set whether the heartbeat messages used for fault tolerance are only sent over the management network.

```
void setFlipperUseBindip(
   Boolean value
)
```

setFlipperUseBindipByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether the heartbeat messages used for fault tolerance are only sent over the management network. This is a location specific function, any action will operate on the specified location.

```
void setFlipperUseBindipByLocation(
   String location
```

```
    Boolean value
)
```

setFlipperVerbose(value) throws InvalidInput, DeploymentError

Set whether the traffic manager should logs all the connectivity tests.

```
void setFlipperVerbose(
    Boolean value
)
```

setFlipperVerboseByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether the traffic manager should logs all the connectivity tests. This is a location specific function, any action will operate on the specified location.

```
void setFlipperVerboseByLocation(
    String location
    Boolean value
)
```

setGLBLoadChangeLimit(value) throws InvalidInput, DeploymentError

Set the maximum change per second to load.

```
void setGLBLoadChangeLimit(
    Unsigned Integer value
)
```

setGLBLoadChangeLimitByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum change per second to load. This is a location specific function, any action will operate on the specified location.

```
void setGLBLoadChangeLimitByLocation(
    String location
    Unsigned Integer value
)
```

setGLBVerbose(value) throws InvalidInput, DeploymentError

Set whether GSLB should log all DNS queries

```
void setGLBVerbose(
    Boolean value
)
```

setGLBVerboseByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether GSLB should log all DNS queries This is a location specific function, any action will operate on the specified location.

```
void setGLBVerboseByLocation(
   String location
   Boolean value
)
```

setHistoricalTrafficDays(value) throws InvalidInput, DeploymentError

Set the length of time historical traffic information is kept for, in days (0=keep indefinitely).

```
void setHistoricalTrafficDays(
   Unsigned Integer value
)
```

setHistoricalTrafficDaysByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time historical traffic information is kept for, in days (0=keep indefinitely). This is a location specific function, any action will operate on the specified location.

```
void setHistoricalTrafficDaysByLocation(
   String location
   Unsigned Integer value
)
```

setIPSessionCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the IP session cache.

```
void setIPSessionCacheSize(
   Unsigned Integer value
)
```

setIPSessionCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the IP session cache. This is a location specific function, any action will operate on the specified location.

```
void setIPSessionCacheSizeByLocation(
```

```
        String location
        Unsigned Integer value
    )
```

setIdleConnectionTimeout(value) throws InvalidInput, DeploymentError

Set how long unused HTTP keepalive connections should be kept before being discarded, in seconds.

```
    void setIdleConnectionTimeout(
        Unsigned Integer value
    )
```

setIdleConnectionTimeoutByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how long unused HTTP keepalive connections should be kept before being discarded, in seconds. This is a location specific function, any action will operate on the specified location.

```
    void setIdleConnectionTimeoutByLocation(
        String location
        Unsigned Integer value
    )
```

setJ2EESessionCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the J2EE session cache.

```
    void setJ2EESessionCacheSize(
        Unsigned Integer value
    )
```

setJ2EESessionCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the J2EE session cache. This is a location specific function, any action will operate on the specified location.

```
    void setJ2EESessionCacheSizeByLocation(
        String location
        Unsigned Integer value
    )
```

setJavaClasspath(value) throws InvalidInput, DeploymentError

Set extra Java CLASSPATH settings required for servlets.

```
void setJavaClasspath(
   String value
)
```

setJavaClasspathByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set extra Java CLASSPATH settings required for servlets. This is a location specific function, any action will operate on the specified location.

```
void setJavaClasspathByLocation(
   String location
   String value
)
```

setJavaCommand(value) throws InvalidInput, DeploymentError

Set the command (and arguments) used to start Java.

```
void setJavaCommand(
   String value
)
```

setJavaCommandByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the command (and arguments) used to start Java. This is a location specific function, any action will operate on the specified location.

```
void setJavaCommandByLocation(
   String location
   String value
)
```

setJavaEnabled(value) throws InvalidInput, DeploymentError

Set whether to enable Java support.

```
void setJavaEnabled(
   Boolean value
)
```

setJavaEnabledByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether to enable Java support. This is a location specific function, any action will operate on the specified location.

```
void setJavaEnabledByLocation(
   String location
   Boolean value
)
```

setJavaLib(value) throws InvalidInput, DeploymentError

Set the location of the java library directory

```
void setJavaLib(
   String value
)
```

setJavaLibByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the location of the java library directory This is a location specific function, any action will operate on the specified location.

```
void setJavaLibByLocation(
   String location
   String value
)
```

setJavaMaxConns(value) throws InvalidInput, DeploymentError

Set the maximum number of Java threads

```
void setJavaMaxConns(
   Unsigned Integer value
)
```

setJavaMaxConnsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of Java threads This is a location specific function, any action will operate on the specified location.

```
void setJavaMaxConnsByLocation(
   String location
   Unsigned Integer value
)
```

setJavaSessionAge(value) throws InvalidInput, DeploymentError

Set the default maximum age of Java session persistence

```
void setJavaSessionAge(
```

```
    Unsigned Integer value
)
```

setJavaSessionAgeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the default maximum age of Java session persistence This is a location specific function, any action will operate on the specified location.

```
void setJavaSessionAgeByLocation(
    String location
    Unsigned Integer value
)
```

setListenQueueSize(value) throws InvalidInput, DeploymentError

Set the size of the listen queue for managing incoming connections.

```
void setListenQueueSize(
    Unsigned Integer value
)
```

setListenQueueSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the size of the listen queue for managing incoming connections. This is a location specific function, any action will operate on the specified location.

```
void setListenQueueSizeByLocation(
    String location
    Unsigned Integer value
)
```

setLogFlushFlushTime(value) throws InvalidInput, DeploymentError

Set the length of time to wait before flushing the request log files for each virtual server, in seconds.

```
void setLogFlushFlushTime(
    Unsigned Integer value
)
```

setLogFlushFlushTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time to wait before flushing the request log files for each virtual server, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setLogFlushFlushTimeByLocation(
   String location
   Unsigned Integer value
)
```

setLogInterval(value) throws InvalidInput, DeploymentError

Set the length of time between log messages for log intensive features e.g. SLM, in seconds.

```
void setLogInterval(
   Unsigned Integer value
)
```

setLogIntervalByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time between log messages for log intensive features e.g. SLM, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setLogIntervalByLocation(
   String location
   Unsigned Integer value
)
```

setLogRate(value) throws InvalidInput, DeploymentError

Set is the maximum number of connection errors logged per second.

```
void setLogRate(
   Unsigned Integer value
)
```

setLogRateByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set is the maximum number of connection errors logged per second. This is a location specific function, any action will operate on the specified location.

```
void setLogRateByLocation(
   String location
   Unsigned Integer value
)
```

setLogReopenTime(value) throws InvalidInput, DeploymentError

Set the length of time to wait before re-opening request log files, to handle log file rotation, in seconds.

```
void setLogReopenTime(
   Unsigned Integer value
)
```

setLogReopenTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time to wait before re-opening request log files, to handle log file rotation, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setLogReopenTimeByLocation(
   String location
   Unsigned Integer value
)
```

setLoginBanner(value) throws InvalidInput, DeploymentError

Set the banner to be shown on the login page and by appliance SSH servers.

```
void setLoginBanner(
   String value
)
```

setMaxAccepting(value) throws InvalidInput, DeploymentError

Set how many traffic manager child processes accept new connections.

```
void setMaxAccepting(
   Unsigned Integer value
)
```

setMaxAcceptingByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how many traffic manager child processes accept new connections. This is a location specific function, any action will operate on the specified location.

```
void setMaxAcceptingByLocation(
   String location
   Unsigned Integer value
)
```

setMaxIdleConnections(value) throws InvalidInput, DeploymentError

Set the maximum number of unused HTTP keepalive connections to all nodes that should maintained for re-use.

```
void setMaxIdleConnections(
   Unsigned Integer value
)
```

setMaxIdleConnectionsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of unused HTTP keepalive connections to all nodes that should maintained for re-use. This is a location specific function, any action will operate on the specified location.

```
void setMaxIdleConnectionsByLocation(
   String location
   Unsigned Integer value
)
```

setMaxKeepalives(value) throws InvalidInput, DeploymentError

setMaxKeepalives is deprecated, please use setMaxIdleConnections instead.

```
void setMaxKeepalives(
   Unsigned Integer value
)
```

setMaxKeepalivesByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setMaxKeepalives is deprecated, please use setMaxIdleConnections instead. This is a location specific function, any action will operate on the specified location.

```
void setMaxKeepalivesByLocation(
   String location
   Unsigned Integer value
)
```

setMaxRetries(value) throws InvalidInput, DeploymentError

This method is now obsolete and is replaced by Pool.setNodeConnectionAttempts.

```
void setMaxRetries(
   Unsigned Integer value
)
```

setMaximumFDCount(value) throws InvalidInput, DeploymentError

Set the maximum number of file descriptors that your traffic manager will allocate

```
void setMaximumFDCount(
   Unsigned Integer value
)
```

setMaximumFDCountByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of file descriptors that your traffic manager will allocate This is a location specific function, any action will operate on the specified location.

```
void setMaximumFDCountByLocation(
   String location
   Unsigned Integer value
)
```

setMonitorNumNodes(value) throws InvalidInput, DeploymentError

Set the maximum number of nodes that can be monitored.

```
void setMonitorNumNodes(
   Unsigned Integer value
)
```

setMonitorNumNodesByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of nodes that can be monitored. This is a location specific function, any action will operate on the specified location.

```
void setMonitorNumNodesByLocation(
   String location
   Unsigned Integer value
)
```

setMultipleAccept(value) throws InvalidInput, DeploymentError

Set whether your traffic manager should try and read multiple new connections each time a new client connects.

```
void setMultipleAccept(
   Boolean value
)
```

setMultipleAcceptByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether your traffic manager should try and read multiple new connections each time a new client connects. This is a location specific function, any action will operate on the specified location.

```
void setMultipleAcceptByLocation(
   String location
   Boolean value
)
```

setNodeConnectionAttempts(value) throws InvalidInput, DeploymentError

This method is now obsolete and is replaced by Pool.setNodeConnectionAttempts.

```
void setNodeConnectionAttempts(
   Unsigned Integer value
)
```

setNodeFailTime(value) throws InvalidInput, DeploymentError

This method is now obsolete and is replaced by Pool.setNodeFailTime.

```
void setNodeFailTime(
   Unsigned Integer value
)
```

setRateClassLimit(value) throws InvalidInput, DeploymentError

Set the maximum number of Rate classes allowed.

```
void setRateClassLimit(
   Unsigned Integer value
)
```

setRateClassLimitByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of Rate classes allowed. This is a location specific function, any action will operate on the specified location.

```
void setRateClassLimitByLocation(
   String location
   Unsigned Integer value
)
```

setRecentConns(value) throws InvalidInput, DeploymentError

Set the details of how many recently closed connections each traffic manager process should save for use with the Connections page.

```
void setRecentConns(
    Unsigned Integer value
)
```

setRecentConnsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the details of how many recently closed connections each traffic manager process should save for use with the Connections page. This is a location specific function, any action will operate on the specified location.

```
void setRecentConnsByLocation(
    String location
    Unsigned Integer value
)
```

setRecentConnsRetainTime(value) throws InvalidInput, DeploymentError

Set for how long a snapshot should be retained on the Connections page.

```
void setRecentConnsRetainTime(
    Unsigned Integer value
)
```

setRecentConnsRetainTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set for how long a snapshot should be retained on the Connections page. This is a location specific function, any action will operate on the specified location.

```
void setRecentConnsRetainTimeByLocation(
    String location
    Unsigned Integer value
)
```

setRecentConnsSnapshotSize(value) throws InvalidInput, DeploymentError

Set the maximum number of connections each traffic manager process should show for a snapshot on the Connections page.

```
void setRecentConnsSnapshotSize(
    Unsigned Integer value
)
```

setRecentConnsSnapshotSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of connections each traffic manager process should show for a snapshot on the Connections page. This is a location specific function, any action will operate on the specified location.

```
void setRecentConnsSnapshotSizeByLocation(
   String location
   Unsigned Integer value
)
```

setSLMClassLimit(value) throws InvalidInput, DeploymentError

Set the maximum number of SLM classes allowed.

```
void setSLMClassLimit(
   Unsigned Integer value
)
```

setSLMClassLimitByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of SLM classes allowed. This is a location specific function, any action will operate on the specified location.

```
void setSLMClassLimitByLocation(
   String location
   Unsigned Integer value
)
```

setSNMPUserCounters(value) throws InvalidInput, DeploymentError

Set the number of user defined SNMP counters.

```
void setSNMPUserCounters(
   Unsigned Integer value
)
```

setSNMPUserCountersByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of user defined SNMP counters. This is a location specific function, any action will operate on the specified location.

```
void setSNMPUserCountersByLocation(
   String location
   Unsigned Integer value
)
```

setSSL3AllowRehandshake(value) throws InvalidInput, DeploymentError

Set whether SSL / TLS re-handshakes are supported.

```
void setSSL3AllowRehandshake(
    GlobalSettings.SSL3AllowRehandshake value
)
```

setSSL3AllowRehandshakeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether SSL / TLS re-handshakes are supported. This is a location specific function, any action will operate on the specified location.

```
void setSSL3AllowRehandshakeByLocation(
    String location
    GlobalSettings.SSL3AllowRehandshake value
)
```

setSSL3Ciphers(value) throws InvalidInput, DeploymentError

Set the list of configured SSL ciphers (available ciphers can be displayed using the command $ZEUSHOME/zxtm/bin/zeus.zxtm -s).

```
void setSSL3Ciphers(
    String value
)
```

setSSL3CiphersByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the list of configured SSL ciphers (available ciphers can be displayed using the command $ZEUSHOME/zxtm/bin/zeus.zxtm -s). This is a location specific function, any action will operate on the specified location.

```
void setSSL3CiphersByLocation(
    String location
    String value
)
```

setSSLDFailureCount(value) throws InvalidInput, DeploymentError

setSSLDFailureCount is deprecated, please use setSSLHardwareFailureCount instead.

```
void setSSLDFailureCount(
    Unsigned Integer value
)
```

setSSLDFailureCountByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setSSLDFailureCount is deprecated, please use setSSLHardwareFailureCount instead. This is a location specific function, any action will operate on the specified location.

```
void setSSLDFailureCountByLocation(
   String location
   Unsigned Integer value
)
```

setSSLDPKCS11Lib(value) throws InvalidInput, DeploymentError

setSSLDPKCS11Lib is deprecated, please use setSSLHardwarePKCS11Lib instead.

```
void setSSLDPKCS11Lib(
   String value
)
```

setSSLDPKCS11LibByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setSSLDPKCS11Lib is deprecated, please use setSSLHardwarePKCS11Lib instead. This is a location specific function, any action will operate on the specified location.

```
void setSSLDPKCS11LibByLocation(
   String location
   String value
)
```

setSSLDPKCS11UserPIN(value) throws InvalidInput, DeploymentError

setSSLDPKCS11UserPIN is deprecated, please use setSSLHardwarePKCS11UserPIN instead.

```
void setSSLDPKCS11UserPIN(
   String value
)
```

setSSLDPKCS11UserPINByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setSSLDPKCS11UserPIN is deprecated, please use setSSLHardwarePKCS11UserPIN instead. This is a location specific function, any action will operate on the specified location.

```
void setSSLDPKCS11UserPINByLocation(
```

```
      String location
      String value
   )
```

setSSLHardwareAccelerator(value) throws InvalidInput, DeploymentError

Set whether your traffic manager should always attempt to use SSL hardware.

```
   void setSSLHardwareAccelerator(
      Boolean value
   )
```

setSSLHardwareAcceleratorByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether your traffic manager should always attempt to use SSL hardware. This is a location specific function, any action will operate on the specified location.

```
   void setSSLHardwareAcceleratorByLocation(
      String location
      Boolean value
   )
```

setSSLHardwareFailureCount(value) throws InvalidInput, DeploymentError

Set the number of consecutive failures from the SSL hardware that will be tolerated before your traffic manager tries to log in again.

```
   void setSSLHardwareFailureCount(
      Unsigned Integer value
   )
```

setSSLHardwareFailureCountByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of consecutive failures from the SSL hardware that will be tolerated before your traffic manager tries to log in again. This is a location specific function, any action will operate on the specified location.

```
   void setSSLHardwareFailureCountByLocation(
      String location
      Unsigned Integer value
   )
```

setSSLHardwarePKCS11Lib(value) throws InvalidInput, DeploymentError

Set the location of the PKCS#11 library supplied by your hardware vendor.

```
void setSSLHardwarePKCS11Lib(
   String value
)
```

setSSLHardwarePKCS11LibByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the location of the PKCS#11 library supplied by your hardware vendor. This is a location specific function, any action will operate on the specified location.

```
void setSSLHardwarePKCS11LibByLocation(
   String location
   String value
)
```

setSSLHardwarePKCS11UserPIN(value) throws InvalidInput, DeploymentError

Set the user PIN for the PKCS token (PKCS#11 devices only)

```
void setSSLHardwarePKCS11UserPIN(
   String value
)
```

setSSLHardwarePKCS11UserPINByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the user PIN for the PKCS token (PKCS#11 devices only) This is a location specific function, any action will operate on the specified location.

```
void setSSLHardwarePKCS11UserPINByLocation(
   String location
   String value
)
```

setSSLHardwareType(value) throws InvalidInput, DeploymentError

Set the device driver library name.

```
void setSSLHardwareType(
   GlobalSettings.SSLHardwareType value
)
```

setSSLHardwareTypeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the device driver library name. This is a location specific function, any action will operate on the specified location.

```
void setSSLHardwareTypeByLocation(
   String location
   GlobalSettings.SSLHardwareType value
)
```

setSSLSessionCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the SSL session cache. This is used to provide persistence based on SSL session IDs.

```
void setSSLSessionCacheSize(
   Unsigned Integer value
)
```

setSSLSessionCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the SSL session cache. This is used to provide persistence based on SSL session IDs. This is a location specific function, any action will operate on the specified location.

```
void setSSLSessionCacheSizeByLocation(
   String location
   Unsigned Integer value
)
```

setSSLSessionIDCacheExpiryTime(value) throws InvalidInput, DeploymentError

Set the length of time that SSL session IDs are stored, in seconds.

```
void setSSLSessionIDCacheExpiryTime(
   Unsigned Integer value
)
```

setSSLSessionIDCacheExpiryTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the length of time that SSL session IDs are stored, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setSSLSessionIDCacheExpiryTimeByLocation(
   String location
   Unsigned Integer value
)
```

setSSLSessionIDCacheSize(value) throws InvalidInput, DeploymentError

Set the number of entries in the SSL session ID cache.

```
void setSSLSessionIDCacheSize(
   Unsigned Integer value
)
```

setSSLSessionIDCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of entries in the SSL session ID cache. This is a location specific function, any action will operate on the specified location.

```
void setSSLSessionIDCacheSizeByLocation(
   String location
   Unsigned Integer value
)
```

setSSLSupportSSL2(value) throws InvalidInput, DeploymentError

Set whether SSLv2 support is enabled.

```
void setSSLSupportSSL2(
   Boolean value
)
```

setSSLSupportSSL2ByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether SSLv2 support is enabled. This is a location specific function, any action will operate on the specified location.

```
void setSSLSupportSSL2ByLocation(
   String location
   Boolean value
)
```

setSSLSupportSSL3(value) throws InvalidInput, DeploymentError

Set whether SSLv3 support is enabled.

```
void setSSLSupportSSL3(
   Boolean value
)
```

setSSLSupportSSL3ByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether SSLv3 support is enabled. This is a location specific function, any action will operate on the specified location.

```
void setSSLSupportSSL3ByLocation(
    String location
    Boolean value
)
```

setSSLSupportTLS1(value) throws InvalidInput, DeploymentError

Set whether TLSv1 support is enabled.

```
void setSSLSupportTLS1(
    Boolean value
)
```

setSSLSupportTLS11(value) throws InvalidInput, DeploymentError

Set whether TLSv1.1 support is enabled.

```
void setSSLSupportTLS11(
    Boolean value
)
```

setSSLSupportTLS11ByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether TLSv1.1 support is enabled. This is a location specific function, any action will operate on the specified location.

```
void setSSLSupportTLS11ByLocation(
    String location
    Boolean value
)
```

setSSLSupportTLS1ByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether TLSv1 support is enabled. This is a location specific function, any action will operate on the specified location.

```
void setSSLSupportTLS1ByLocation(
    String location
    Boolean value
)
```

setSharedPoolSize(value) throws InvalidInput, DeploymentError

Set is the size of shared memory pool to be used for shared storage across worker processes.

```
void setSharedPoolSize(
    String value
)
```

setSharedPoolSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set is the size of shared memory pool to be used for shared storage across worker processes. This is a location specific function, any action will operate on the specified location.

```
void setSharedPoolSizeByLocation(
    String location
    String value
)
```

setSoapIdleMinutes(value) throws InvalidInput, DeploymentError

Set the number of minutes the SOAP server remain idle before exiting

```
void setSoapIdleMinutes(
    Unsigned Integer value
)
```

setSoapIdleMinutesByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of minutes the SOAP server remain idle before exiting This is a location specific function, any action will operate on the specified location.

```
void setSoapIdleMinutesByLocation(
    String location
    Unsigned Integer value
)
```

setSocketOptimizations(value) throws InvalidInput, DeploymentError

Set whether potential network socket optimisations should be used.

```
void setSocketOptimizations(
    GlobalSettings.SocketOptimizations value
)
```

setSocketOptimizationsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether potential network socket optimisations should be used. This is a location specific function, any action will operate on the specified location.

```
void setSocketOptimizationsByLocation(
   String location
   GlobalSettings.SocketOptimizations value
)
```

setSsldAccel(value) throws InvalidInput, DeploymentError

setSsldAccel is deprecated, please use setSSLHardwareAccelerator instead.

```
void setSsldAccel(
   Boolean value
)
```

setSsldAccelByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setSsldAccel is deprecated, please use setSSLHardwareAccelerator instead. This is a location specific function, any action will operate on the specified location.

```
void setSsldAccelByLocation(
   String location
   Boolean value
)
```

setSsldLibrary(value) throws InvalidInput, DeploymentError

setSsldLibrary is deprecated, please use setSSLHardwareType instead.

```
void setSsldLibrary(
   GlobalSettings.SsldLibrary value
)
```

setSsldLibraryByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

setSsldLibrary is deprecated, please use setSSLHardwareType instead. This is a location specific function, any action will operate on the specified location.

```
void setSsldLibraryByLocation(
   String location
   GlobalSettings.SsldLibrary value
)
```

setStateSyncTime(value) throws InvalidInput, DeploymentError

Set how often the cache state is propagated to other traffic managers in the cluster, in seconds.

```
void setStateSyncTime(
    Unsigned Integer value
)
```

setStateSyncTimeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set how often the cache state is propagated to other traffic managers in the cluster, in seconds. This is a location specific function, any action will operate on the specified location.

```
void setStateSyncTimeByLocation(
    String location
    Unsigned Integer value
)
```

setStateSyncTimeout(value) throws InvalidInput, DeploymentError

Set the timeout for state propagation between cluster members, in seconds

```
void setStateSyncTimeout(
    Unsigned Integer value
)
```

setStateSyncTimeoutByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the timeout for state propagation between cluster members, in seconds This is a location specific function, any action will operate on the specified location.

```
void setStateSyncTimeoutByLocation(
    String location
    Unsigned Integer value
)
```

setSystemReadBufferSize(value) throws InvalidInput, DeploymentError

Set the size of the operating system's read buffer, in bytes (0 means use the system default).

```
void setSystemReadBufferSize(
    Unsigned Integer value
)
```

setSystemReadBufferSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the size of the operating system's read buffer, in bytes (0 means use the system default). This is a location specific function, any action will operate on the specified location.

```
void setSystemReadBufferSizeByLocation(
   String location
   Unsigned Integer value
)
```

setSystemWriteBufferSize(value) throws InvalidInput, DeploymentError

Set the size of the operating system's write buffer, in bytes (0 means use the system default).

```
void setSystemWriteBufferSize(
   Unsigned Integer value
)
```

setSystemWriteBufferSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the size of the operating system's write buffer, in bytes (0 means use the system default). This is a location specific function, any action will operate on the specified location.

```
void setSystemWriteBufferSizeByLocation(
   String location
   Unsigned Integer value
)
```

setTrafficIPGroupLimit(value) throws InvalidInput, DeploymentError

Set the maximum number of Traffic IP Groups allowed.

```
void setTrafficIPGroupLimit(
   Unsigned Integer value
)
```

setTrafficIPGroupLimitByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of Traffic IP Groups allowed. This is a location specific function, any action will operate on the specified location.

```
void setTrafficIPGroupLimitByLocation(
   String location
```

```
      Unsigned Integer value
   )
```

setTrafficScriptMemoryWarning(value) throws InvalidInput, DeploymentError

Set the amount of buffered network data a TrafficScript rule can buffer before a warning is logged, in bytes.

```
   void setTrafficScriptMemoryWarning(
      Unsigned Integer value
   )
```

setTrafficScriptMemoryWarningByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the amount of buffered network data a TrafficScript rule can buffer before a warning is logged, in bytes. This is a location specific function, any action will operate on the specified location.

```
   void setTrafficScriptMemoryWarningByLocation(
      String location
      Unsigned Integer value
   )
```

setTrafficscriptArrayElements(value) throws InvalidInput, DeploymentError

Set the number of array elements that can be stored before additional memory is allocated.

```
   void setTrafficscriptArrayElements(
      Unsigned Integer value
   )
```

setTrafficscriptArrayElementsByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of array elements that can be stored before additional memory is allocated. This is a location specific function, any action will operate on the specified location.

```
   void setTrafficscriptArrayElementsByLocation(
      String location
      Unsigned Integer value
   )
```

setTrafficscriptDataSize(value) throws InvalidInput, DeploymentError

Set the maximum size of the TrafficScript shared data pool (specified as a percentage of system RAM, e.g. '5%', or an absolute size, e.g. 200MB)

```
void setTrafficscriptDataSize(
   String value
)
```

setTrafficscriptDataSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum size of the TrafficScript shared data pool (specified as a percentage of system RAM, e.g. '5%', or an absolute size, e.g. 200MB) This is a location specific function, any action will operate on the specified location.

```
void setTrafficscriptDataSizeByLocation(
   String location
   String value
)
```

setTrafficscriptMaxInstr(value) throws InvalidInput, DeploymentError

Set the maximum number of instructions a TrafficScript rule will run before being aborted.

```
void setTrafficscriptMaxInstr(
   Unsigned Integer value
)
```

setTrafficscriptMaxInstrByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of instructions a TrafficScript rule will run before being aborted. This is a location specific function, any action will operate on the specified location.

```
void setTrafficscriptMaxInstrByLocation(
   String location
   Unsigned Integer value
)
```

setTrafficscriptRegexCacheSize(value) throws InvalidInput, DeploymentError

Set the number of regular expressions to cache

```
void setTrafficscriptRegexCacheSize(
   Unsigned Integer value
)
```

setTrafficscriptRegexCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the number of regular expressions to cache This is a location specific function, any action will operate on the specified location.

```
void setTrafficscriptRegexCacheSizeByLocation(
   String location
   Unsigned Integer value
)
```

setTrafficscriptVariablePoolUse(value) throws InvalidInput, DeploymentError

Set whether the 'pool.use' and 'pool.select' TrafficScript functions accept variables as well as literal strings.

```
void setTrafficscriptVariablePoolUse(
   Boolean value
)
```

setTrafficscriptVariablePoolUseByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether the 'pool.use' and 'pool.select' TrafficScript functions accept variables as well as literal strings. This is a location specific function, any action will operate on the specified location.

```
void setTrafficscriptVariablePoolUseByLocation(
   String location
   Boolean value
)
```

setUniversalSessionCacheSize(value) throws InvalidInput, DeploymentError

Set the maximum number of entries in the universal session cache.

```
void setUniversalSessionCacheSize(
   Unsigned Integer value
)
```

setUniversalSessionCacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of entries in the universal session cache. This is a location specific function, any action will operate on the specified location.

```
void setUniversalSessionCacheSizeByLocation(
   String location
   Unsigned Integer value
```

```
)
```

setWebcacheDisk(value) throws InvalidInput, DeploymentError

Set whether the webcache is stored on disk

```
void setWebcacheDisk(
   Boolean value
)
```

setWebcacheDiskByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether the webcache is stored on disk This is a location specific function, any action will operate on the specified location.

```
void setWebcacheDiskByLocation(
   String location
   Boolean value
)
```

setWebcacheDiskDir(value) throws InvalidInput, DeploymentError

Set the disk cache location

```
void setWebcacheDiskDir(
   String value
)
```

setWebcacheDiskDirByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the disk cache location This is a location specific function, any action will operate on the specified location.

```
void setWebcacheDiskDirByLocation(
   String location
   String value
)
```

setWebcacheMaxFileNum(value) throws InvalidInput, DeploymentError

Set the maximum number of files that can be stored in the web cache

```
void setWebcacheMaxFileNum(
   Unsigned Integer value
)
```

setWebcacheMaxFileNumByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum number of files that can be stored in the web cache This is a location specific function, any action will operate on the specified location.

```
void setWebcacheMaxFileNumByLocation(
    String location
    Unsigned Integer value
)
```

setWebcacheMaxFileSize(value) throws InvalidInput, DeploymentError

Set the largest size of a cacheable object, relative to the total cache size, e.g. '2%', or as an absolute size in kB (default), MB or GB, e.g. '20MB'.

```
void setWebcacheMaxFileSize(
    String value
)
```

setWebcacheMaxFileSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the largest size of a cacheable object, relative to the total cache size, e.g. '2%', or as an absolute size in kB (default), MB or GB, e.g. '20MB'. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheMaxFileSizeByLocation(
    String location
    String value
)
```

setWebcacheNormalizeQuery(value) throws InvalidInput, DeploymentError

Set whether the assignment sub-strings in the parameter string are put into alphabetical order.

```
void setWebcacheNormalizeQuery(
    Boolean value
)
```

setWebcacheNormalizeQueryByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether the assignment sub-strings in the parameter string are put into alphabetical order. This is a location specific function, any action will operate on the specified location.

```
void setWebcacheNormalizeQueryByLocation(
    String location
```

```
      Boolean value
   )
```

setWebcacheSize(value) throws InvalidInput, DeploymentError

Set the maximum size of the HTTP web page cache, (specified as a percentage of system RAM, e.g. '20%', or an absolute size, e.g. 200MB)

```
   void setWebcacheSize(
      String value
   )
```

setWebcacheSizeByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set the maximum size of the HTTP web page cache, (specified as a percentage of system RAM, e.g. '20%', or an absolute size, e.g. 200MB) This is a location specific function, any action will operate on the specified location.

```
   void setWebcacheSizeByLocation(
      String location
      String value
   )
```

setWebcacheVerbose(value) throws InvalidInput, DeploymentError

Set whether an X-Cache-Info header to show cacheability should be added.

```
   void setWebcacheVerbose(
      Boolean value
   )
```

setWebcacheVerboseByLocation(location, value) throws InvalidInput, DeploymentError, ObjectDoesNotExist

Set whether an X-Cache-Info header to show cacheability should be added. This is a location specific function, any action will operate on the specified location.

```
   void setWebcacheVerboseByLocation(
      String location
      Boolean value
   )
```

6.17.2 Enumerations

GlobalSettings.ErrorLevel

```
   enum GlobalSettings.ErrorLevel {
```

```
    # ERR_FATAL
    fatal,

    # ERR_SERIOUS
    serious,

    # ERR_WARN
    warn,

    # ERR_INFO
    info
}
```

GlobalSettings.FlipperHeartbeatMethod

```
enum GlobalSettings.FlipperHeartbeatMethod {
    # multicast
    multicast,

    # unicast
    unicast
}
```

GlobalSettings.SSL3AllowRehandshake

```
enum GlobalSettings.SSL3AllowRehandshake {
    # Always allow
    always,

    # Allow safe re-handshakes
    safe,

    # Only if client uses RFC 5746 (Secure Renegotiation
    # Extension)
    rfc5746,

    # Never allow
    never
}
```

GlobalSettings.SSLHardwareType

```
enum GlobalSettings.SSLHardwareType {
    # None
    none,

    # PKCS#11 (e.g. nCipher NetHSM, Sun SCA 6000)
    pkcs11,
```

```
    # Cavium Networks CN1000
    cn1000,

    # Cavium Networks CN2000
    cn2000
}
```

GlobalSettings.SocketOptimizations

```
enum GlobalSettings.SocketOptimizations {
    # auto
    auto,

    # Yes
    Yes,

    # No
    No
}
```

GlobalSettings.SsldLibrary

```
enum GlobalSettings.SsldLibrary {
    # None
    none,

    # PKCS#11 (e.g. nCipher NetHSM, Sun SCA 6000)
    pkcs11,

    # Cavium Networks CN1000
    cn1000,

    # Cavium Networks CN2000
    cn2000
}
```

6.18 Conf.Extra

URI: `http://soap.zeus.com/zxtm/1.1/Conf/Extra/`

The Conf.Extra interface allows management of the files stored in the conf/extra directory. These files can be read in by rules, and used as error pages to be sent to clients. This interface allows creating, deleting and retrieving the files.

6.18.1 Methods

deleteFile(names) throws ObjectDoesNotExist

Delete the named files from the conf/extra directory.

```
void deleteFile(
   String[] names
)
```

downloadFile(name) throws ObjectDoesNotExist

Download the named from from the conf/extra directory

```
Binary Data downloadFile(
   String name
)
```

getFileNames()

Get the names of all the files stored in the conf/extra directory.

```
String[] getFileNames()
```

uploadFile(name, content) throws InvalidObjectName

Uploads a new file into the conf/extra, overwriting the file if it already exists.

```
void uploadFile(
   String name
   Binary Data content
)
```

6.19 Diagnose

URI: http://soap.zeus.com/zxtm/1.1/Diagnose/

The Diagnose interface provides information about errors and problems in the system.

6.19.1 Methods

activateTrafficManagers(hostnames) throws InvalidInput

Activate traffic managers that have recovered from failures and are ready to start taking Traffic IPs.

```
void activateTrafficManagers(
   String[] hostnames
)
```

diagnoseSystem()

Provides all diagnostic information about the system.

```
Diagnose.ErrorInfo diagnoseSystem()
```

getInactiveTrafficManagers()

List the traffic managers that have recovered from failures and are ready to start taking Traffic IPs.

```
String[] getInactiveTrafficManagers()
```

getTechnicalSupportReport()

Download a technical support report suitable for providing to your support provider to help diagnose problems.

```
Binary Data getTechnicalSupportReport()
```

6.19.2 Structures

Diagnose.AgeError

This structure combines an error message with its age in seconds

```
struct Diagnose.AgeError {
    # Seconds since the error occurred
    Integer age;

    # error message
    String error;
}
```

Diagnose.ConfigError

This structure contains information about configuration errors.

```
struct Diagnose.ConfigError {
    # The file where the error has occurred.
    String filename;

    # The faulty configuration key
    String ConfigKey;

    # Severity of the error
    Diagnose.ErrLevel severity;
```

```
        # Date when the error occurred
        Time DetectionDate;

        # A human readable description of the error
        String description;
    }
```

Diagnose.ErrorInfo

This structure combines configuration, node, and flipper errors as well as a list of statuses (for an appliance).

```
struct Diagnose.ErrorInfo {
    # The list of traffic managers that could not be contacted.
    String[] NotReachableTrafficManagers;

    # The list of configuration errors.
    Diagnose.ConfigError[] ConfigErrors;

    # The list of flipper errors.
    Diagnose.FlipperError[] FlipperErrors;

    # The list of failed nodes.
    Diagnose.FailedNode[] FailedNodes;

    # The list of system status values.
    Diagnose.SystemStatus[] SystemStatuses;
}
```

Diagnose.FailedNode

This structure contains information about Flipper errors.

```
struct Diagnose.FailedNode {
    # The name of the node that has failed.
    String node;

    # IP address in standard IPv4 or IPv6 notation.
    String IPAddress;

    # The port number of the node that has failed.
    Integer port;

    # The pool in which this node exists.
    String pool;

    # Time that the failure first occurred.
    Time InitialFailureTime;

    # The last time an attempt was made to connect to the node.
```

```
    Time LastConnectionAttempt;

    # The last received error message.
    String ErrorMessage;
}
```

Diagnose.FlipperError

This structure contains information about Flipper errors.

```
struct Diagnose.FlipperError {
    # The name of the affected machine.
    String machine;

    # IP address in standard IPv4 or IPv6 notation.
    String IPAddress;

    # All error messages for that machine.
    Diagnose.AgeError[] errors;
}
```

Diagnose.SystemStatus

Status information about the hardware in an appliance is reported by instances of this structure.

```
struct Diagnose.SystemStatus {
    # The component this object refers to
    String component;

    # The severity level
    Diagnose.ErrLevel severity;

    # Human-readable description of the status
    String message;
}
```

6.19.3 Enumerations

Diagnose.ErrLevel

This enumeration defines the possible severity levels of an error.

```
enum Diagnose.ErrLevel {
    # A fatal error, causes program to die/crash/fail to startup.
    ERR_FATAL,

    # A serious, unexpected error that shouldn't occur under
    # normal conditions. Conditions which will prevent the server
    # from operating properly and should be brought to the
```

```
                # webmaster's attention immediately
                ERR_SERIOUS,

                # something which should be brought to the attention of the
                # webmaster, but not immediately.
                ERR_WARN,

                # Minor things that might be of interest e.g. access denied.
                ERR_INFO
            }
```

6.20 System.Backups

URI: `http://soap.zeus.com/zxtm/1.0/System/Backups/`

The Backups interfaces provide operations on saved configuration backup archives.

6.20.1 Methods

createBackup(name, description) throws ObjectAlreadyExists, InvalidObjectName

Create backup archive based on the current configuration

```
    void createBackup(
        String name
        String description
    )
```

deleteAllBackups()

Delete all the backups

```
    void deleteAllBackups()
```

deleteBackups(names) throws ObjectDoesNotExist

delete a list of one or more backups

```
    void deleteBackups(
        String[] names
    )
```

downloadBackup(name) throws ObjectDoesNotExist

Download a backup archive file

```
    Binary Data downloadBackup(
```

```
        String name
    )
```

getBackupDetails(names)

Get details for a list of one or more backups.

```
System.Backups.Backup[] getBackupDetails(
    String[] names
)
```

listAllBackups()

List the details for all backup archives.

```
System.Backups.Backup[] listAllBackups()
```

restoreBackup(name) throws ObjectDoesNotExist

Restore the named backup archive to be the current configuration

```
void restoreBackup(
    String name
)
```

uploadBackup(file) throws InvalidObjectName, ObjectAlreadyExists, InvalidInput

Import a backup archive file into the system

```
void uploadBackup(
    Binary Data file
)
```

6.20.2 Structures

System.Backups.Backup

This structure contains the information for each configuration backup archive.

```
struct System.Backups.Backup {
    # The backup filename.
    String name;

    # The description for this backup.
    String description;

    # The date this backup was created.
```

```
        Time date;

        # The version of this backup archive.
        String version;
    }
```

6.21 Alerting.EventType

URI: `http://soap.zeus.com/zxtm/1.0/Alerting/EventType/`

Alerting.EventType is an interface that allows you to manage event types. Event Types are groups of events and are associated with a list of actions that are invoked when one of the events in the Event Type is triggered.

6.21.1 Methods

addCloudcredentialNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Cloud Credentials that will trigger the specified event types. If the event type has no Cloud Credentials names configured, all objects of this type will match.

```
void addCloudcredentialNames(
    String[] names
    String[][] objects
)
```

addCustomEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Adds custom events the specified event types will trigger on. Custom events are generated by TrafficScript using the event.emit function. To match all custom events, include '*' in the passed array.

```
void addCustomEvents(
    String[] names
    String[][] events
)
```

addEventType(names, eventtypes) throws ObjectAlreadyExists, InvalidObjectName, InvalidInput, DeploymentError

Add an event type that will cause an action to be triggered when its conditions are met.

```
void addEventType(
    String[] names
    Alerting.EventType.EventType[] eventtypes
)
```

addEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Adds events to an event type. An event is something that must occur for the associated actions to be triggered (only one event needs to happen to trigger the actions). At least one event must be specified.

```
void addEvents(
    String[] names
    Alerting.EventType.Event[][] events
)
```

addLicensekeyNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of License Key that will trigger the specified event types. If the event type has no License Key names configured, all objects of this type will match.

```
void addLicensekeyNames(
    String[] names
    String[][] objects
)
```

addLocationNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Location that will trigger the specified event types. If the event type has no Location names configured, all objects of this type will match.

```
void addLocationNames(
    String[] names
    String[][] objects
)
```

addMappedActions(names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add an action that will be run when this event type is triggered.

```
void addMappedActions(
    String[] names
    String[][] values
)
```

addMonitorNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Monitor that will trigger the specified event types. If the event type has no Monitor names configured, all objects of this type will match.

```
void addMonitorNames(
    String[] names
    String[][] objects
)
```

addNodeNames(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Node that will trigger the specified event types. If the event type has no Node names configured, all objects of this type will match.

```
void addNodeNames(
    String[] names
    String[][] events
)
```

addPoolNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Pool that will trigger the specified event types. If the event type has no Pool names configured, all objects of this type will match.

```
void addPoolNames(
    String[] names
    String[][] objects
)
```

addProtectionNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Service Protection Class that will trigger the specified event types. If the event type has no Service Protection Class names configured, all objects of this type will match.

```
void addProtectionNames(
    String[] names
    String[][] objects
)
```

addRuleNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Rule that will trigger the specified event types. If the event type has no Rule names configured, all objects of this type will match.

```
void addRuleNames(
    String[] names
    String[][] objects
)
```

addServiceNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of GLB Service that will trigger the specified event types. If the event type has no GLB Service names configured, all objects of this type will match.

```
void addServiceNames(
    String[] names
    String[][] objects
)
```

addSlmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of SLM Class that will trigger the specified event types. If the event type has no SLM Class names configured, all objects of this type will match.

```
void addSlmNames(
    String[] names
    String[][] objects
)
```

addVserverNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Virtual Server that will trigger the specified event types. If the event type has no Virtual Server names configured, all objects of this type will match.

```
void addVserverNames(
    String[] names
    String[][] objects
)
```

addZxtmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Add the names of Traffic Manager that will trigger the specified event types. If the event type has no Traffic Manager names configured, all objects of this type will match.

```
void addZxtmNames(
    String[] names
    String[][] objects
)
```

copyEventType(names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError

Copy each of the named event types.

```
void copyEventType(
    String[] names
    String[] new_names
)
```

deleteEventType(names) throws ObjectDoesNotExist, DeploymentError

Removes one or more event types.

```
void deleteEventType(
    String[] names
)
```

getCloudcredentialNames(names) throws ObjectDoesNotExist

Get the names of Cloud Credentials that will trigger the specified event types. If the event type has no Cloud Credentials names configured, all objects of this type will match.

```
String[][] getCloudcredentialNames(
    String[] names
)
```

getCustomEvents(names) throws ObjectDoesNotExist

Gets the custom events of the specified event types. Custom events are generated by TrafficScript using the event.emit function. If '*' is returned, all custom events will trigger this event type.

```
String[][] getCustomEvents(
    String[] names
)
```

getEventType(names) throws ObjectDoesNotExist

Returns a set of event type objects for the specified names.

```
Alerting.EventType.EventType[] getEventType(
   String[] names
)
```

getEventTypeNames()

Returns the names of all event types in the system.

```
String[] getEventTypeNames()
```

getEvents(names) throws ObjectDoesNotExist

Gets an event type's events. An event is something that must occur for the associated actions to be triggered (only one event needs to happen to trigger the actions). At least one event must be specified.

```
Alerting.EventType.Event[][] getEvents(
   String[] names
)
```

getLicensekeyNames(names) throws ObjectDoesNotExist

Get the names of License Key that will trigger the specified event types. If the event type has no License Key names configured, all objects of this type will match.

```
String[][] getLicensekeyNames(
   String[] names
)
```

getLocationNames(names) throws ObjectDoesNotExist

Get the names of Location that will trigger the specified event types. If the event type has no Location names configured, all objects of this type will match.

```
String[][] getLocationNames(
   String[] names
)
```

getMappedActions(names) throws ObjectDoesNotExist

Get an action that will be run when this event type is triggered.

```
String[][] getMappedActions(
   String[] names
)
```

getMonitorNames(names) throws ObjectDoesNotExist

Get the names of Monitor that will trigger the specified event types. If the event type has no Monitor names configured, all objects of this type will match.

```
String[][] getMonitorNames(
   String[] names
)
```

getNodeNames(names) throws ObjectDoesNotExist

Get the names of Node that will trigger the specified event types. If the event type has no Node names configured, all objects of this type will match.

```
String[][] getNodeNames(
   String[] names
)
```

getNote(names) throws ObjectDoesNotExist

Get the note for each of the named Event Types.

```
String[] getNote(
   String[] names
)
```

getPoolNames(names) throws ObjectDoesNotExist

Get the names of Pool that will trigger the specified event types. If the event type has no Pool names configured, all objects of this type will match.

```
String[][] getPoolNames(
   String[] names
)
```

getProtectionNames(names) throws ObjectDoesNotExist

Get the names of Service Protection Class that will trigger the specified event types. If the event type has no Service Protection Class names configured, all objects of this type will match.

```
String[][] getProtectionNames(
   String[] names
)
```

getRuleNames(names) throws ObjectDoesNotExist

Get the names of Rule that will trigger the specified event types. If the event type has no Rule names configured, all objects of this type will match.

```
String[][] getRuleNames(
   String[] names
)
```

getServiceNames(names) throws ObjectDoesNotExist

Get the names of GLB Service that will trigger the specified event types. If the event type has no GLB Service names configured, all objects of this type will match.

```
String[][] getServiceNames(
   String[] names
)
```

getSlmNames(names) throws ObjectDoesNotExist

Get the names of SLM Class that will trigger the specified event types. If the event type has no SLM Class names configured, all objects of this type will match.

```
String[][] getSlmNames(
   String[] names
)
```

getVserverNames(names) throws ObjectDoesNotExist

Get the names of Virtual Server that will trigger the specified event types. If the event type has no Virtual Server names configured, all objects of this type will match.

```
String[][] getVserverNames(
   String[] names
)
```

getZxtmNames(names) throws ObjectDoesNotExist

Get the names of Traffic Manager that will trigger the specified event types. If the event type has no Traffic Manager names configured, all objects of this type will match.

```
String[][] getZxtmNames(
   String[] names
)
```

removeCloudcredentialNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Cloud Credentials that will trigger the specified event types. If the event type has no Cloud Credentials names configured, all objects of this type will match.

```
void removeCloudcredentialNames(
   String[] names
   String[][] objects
)
```

removeCustomEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Removes custom events from the specified event types. Custom events are generated by TrafficScript using the event.emit function. If you pass '*', all custom events will be removed.

```
void removeCustomEvents(
   String[] names
   String[][] events
)
```

removeEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Removes events from the event type. An event is something that must occur for the associated actions to be triggered (only one event needs to happen to trigger the actions). At least one event must be specified.

```
void removeEvents(
   String[] names
   Alerting.EventType.Event[][] events
)
```

removeLicensekeyNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of License Key that will trigger the specified event types. If the event type has no License Key names configured, all objects of this type will match.

```
void removeLicensekeyNames(
   String[] names
   String[][] objects
)
```

removeLocationNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Location that will trigger the specified event types. If the event type has no Location names configured, all objects of this type will match.

```
void removeLocationNames(
   String[] names
   String[][] objects
)
```

removeMappedActions(names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove an action that will be run when this event type is triggered.

```
void removeMappedActions(
   String[] names
   String[][] values
)
```

removeMonitorNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Monitor that will trigger the specified event types. If the event type has no Monitor names configured, all objects of this type will match.

```
void removeMonitorNames(
   String[] names
   String[][] objects
)
```

removeNodeNames(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Node that will trigger the specified event types. If the event type has no Node names configured, all objects of this type will match.

```
void removeNodeNames(
   String[] names
   String[][] events
)
```

removePoolNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Pool that will trigger the specified event types. If the event type has no Pool names configured, all objects of this type will match.

```
void removePoolNames(
   String[] names
   String[][] objects
)
```

removeProtectionNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Service Protection Class that will trigger the specified event types. If the event type has no Service Protection Class names configured, all objects of this type will match.

```
void removeProtectionNames(
   String[] names
   String[][] objects
)
```

removeRuleNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Rule that will trigger the specified event types. If the event type has no Rule names configured, all objects of this type will match.

```
void removeRuleNames(
   String[] names
   String[][] objects
)
```

removeServiceNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of GLB Service that will trigger the specified event types. If the event type has no GLB Service names configured, all objects of this type will match.

```
void removeServiceNames(
   String[] names
   String[][] objects
)
```

removeSlmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of SLM Class that will trigger the specified event types. If the event type has no SLM Class names configured, all objects of this type will match.

```
void removeSlmNames(
   String[] names
   String[][] objects
```

```
)
```

removeVserverNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Virtual Server that will trigger the specified event types. If the event type has no Virtual Server names configured, all objects of this type will match.

```
void removeVserverNames(
   String[] names
   String[][] objects
)
```

removeZxtmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Remove the names of Traffic Manager that will trigger the specified event types. If the event type has no Traffic Manager names configured, all objects of this type will match.

```
void removeZxtmNames(
   String[] names
   String[][] objects
)
```

renameEventType(names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError, InvalidOperation

Rename each of the named event types.

```
void renameEventType(
   String[] names
   String[] new_names
)
```

setCloudcredentialNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Cloud Credentials that will trigger the specified event types. If the event type has no Cloud Credentials names configured, all objects of this type will match.

```
void setCloudcredentialNames(
   String[] names
   String[][] objects
)
```

setCustomEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Gets the custom events the specified event types will trigger on. Custom events are generated by TrafficScript using the event.emit function. To match all custom events, include '*' in the passed array.

```
void setCustomEvents(
   String[] names
   String[][] events
)
```

setEvents(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Sets an event type's events (all old events will be removed). An event is something that must occur for the associated actions to be triggered (only one event needs to happen to trigger the actions). At least one event must be specified.

```
void setEvents(
   String[] names
   Alerting.EventType.Event[][] events
)
```

setLicensekeyNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of License Key that will trigger the specified event types. If the event type has no License Key names configured, all objects of this type will match.

```
void setLicensekeyNames(
   String[] names
   String[][] objects
)
```

setLocationNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Location that will trigger the specified event types. If the event type has no Location names configured, all objects of this type will match.

```
void setLocationNames(
   String[] names
   String[][] objects
)
```

setMappedActions(names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set an action that will be run when this event type is triggered.

```
void setMappedActions(
   String[] names
   String[][] values
)
```

setMonitorNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Monitor that will trigger the specified event types. If the event type has no Monitor names configured, all objects of this type will match.

```
void setMonitorNames(
   String[] names
   String[][] objects
)
```

setNodeNames(names, events) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Node that will trigger the specified event types. If the event type has no Node names configured, all objects of this type will match.

```
void setNodeNames(
   String[] names
   String[][] events
)
```

setNote(names, values) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the note for each of the named Event Types.

```
void setNote(
   String[] names
   String[] values
)
```

setPoolNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Pool that will trigger the specified event types. If the event type has no Pool names configured, all objects of this type will match.

```
void setPoolNames(
```

```
   String[] names
   String[][] objects
)
```

setProtectionNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Service Protection Class that will trigger the specified event types. If the event type has no Service Protection Class names configured, all objects of this type will match.

```
void setProtectionNames(
   String[] names
   String[][] objects
)
```

setRuleNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Rule that will trigger the specified event types. If the event type has no Rule names configured, all objects of this type will match.

```
void setRuleNames(
   String[] names
   String[][] objects
)
```

setServiceNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of GLB Service that will trigger the specified event types. If the event type has no GLB Service names configured, all objects of this type will match.

```
void setServiceNames(
   String[] names
   String[][] objects
)
```

setSlmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of SLM Class that will trigger the specified event types. If the event type has no SLM Class names configured, all objects of this type will match.

```
void setSlmNames(
   String[] names
   String[][] objects
)
```

setVserverNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Virtual Server that will trigger the specified event types. If the event type has no Virtual Server names configured, all objects of this type will match.

```
void setVserverNames(
   String[] names
   String[][] objects
)
```

setZxtmNames(names, objects) throws InvalidInput, ObjectDoesNotExist, InvalidOperation, DeploymentError

Set the names of Traffic Manager that will trigger the specified event types. If the event type has no Traffic Manager names configured, all objects of this type will match.

```
void setZxtmNames(
   String[] names
   String[][] objects
)
```

6.21.2 Structures

Alerting.EventType.EventType

A set of conditions that when met causes an action to be run.

```
struct Alerting.EventType.EventType {
   # The events that will trigger the associated actions.
   Alerting.EventType.Event[] events;

   # The names of all the custom events you want to trigger this
   # event type.
   String[] customEvents;

   # The names of all the actions mapped to this custom event.
   String[] mappedActions;

   # The names of all the Service Protection Classes that should
   # trigger this event type. If this is an empty array all
   # objects of this type will be matched.
   String[] protectionNames;

   # The names of all the Virtual Servers that should trigger
   # this event type. If this is an empty array all objects of
   # this type will be matched.
   String[] vserverNames;
```

```
# The names of all the SLM Classes that should trigger this
# event type. If this is an empty array all objects of this
# type will be matched.
String[] slmNames;

# The names of all the Locations that should trigger this
# event type. If this is an empty array all objects of this
# type will be matched.
String[] locationNames;

# The names of all the Monitors that should trigger this event

6.22 Alerting.Action

URI: `http://soap.zeus.com/zxtm/1.0/Alerting/Action/`

Alerting.Action is an interface that allows you to add actions that are run by event types.

6.22.1 Methods

addAction(names, types) throws InvalidInput, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Add a action that can be run by an event.

```
        void addAction(
          String[] names
```

```
    Alerting.Action.Type[] types
)
```

addScriptArguments(names, arguments) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Adds a set of arguments to the specified actions. The actions specified must be of type 'program'.

```
void addScriptArguments(
    String[] names
    Alerting.Action.Argument[][] arguments
)
```

copyAction(names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError

Copy each of the named actions.

```
void copyAction(
    String[] names
    String[] new_names
)
```

deleteAction(names) throws ObjectDoesNotExist, ObjectInUse, DeploymentError

Deletes each of the named actions.

```
void deleteAction(
    String[] names
)
```

deleteActionProgram(names) throws ObjectDoesNotExist, DeploymentError, ObjectInUse

Delete the named action programs.

```
void deleteActionProgram(
    String[] names
)
```

downloadActionProgram(name) throws ObjectDoesNotExist

Download the named action program.

```
Binary Data downloadActionProgram(
    String name
```

```
)
```

getActionNames()

Get the names of all available actions.

```
String[] getActionNames()
```

getActionNamesOfType(type)

Get the names of all actions of the specified type.

```
String[] getActionNamesOfType(
   Alerting.Action.Type type
)
```

getActionProgramNames()

Get the names of all the uploaded action programs. These are the programs that can be executed by custom program actions.

```
String[] getActionProgramNames()
```

getActionType(names) throws InvalidOperation, ObjectDoesNotExist

Returns the type of each of the named actions.

```
Alerting.Action.Type[] getActionType(
   String[] names
)
```

getEmailRecipients(names) throws InvalidOperation, ObjectDoesNotExist

Get the address the alert emails are sent from.

```
String[] getEmailRecipients(
   String[] names
)
```

getEmailRecipientsByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the address the alert emails are sent from. This is a location specific function, any action will operate on the specified location.

```
String[] getEmailRecipientsByLocation(
   String location
   String[] names
```

)

getEmailSMTPServer(names) throws InvalidOperation, ObjectDoesNotExist

Get the SMTP server used to send alert emails for the specified actions.

```
String[] getEmailSMTPServer(
   String[] names
)
```

getEmailSMTPServerByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the SMTP server used to send alert emails for the specified actions. This is a location specific function, any action will operate on the specified location.

```
String[] getEmailSMTPServerByLocation(
   String location
   String[] names
)
```

getEmailSender(names) throws InvalidOperation, ObjectDoesNotExist

Get the specified email addresses to the recipient list for the specified actions.

```
String[] getEmailSender(
   String[] names
)
```

getEmailSenderByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the specified email addresses to the recipient list for the specified actions. This is a location specific function, any action will operate on the specified location.

```
String[] getEmailSenderByLocation(
   String location
   String[] names
)
```

getLogFilePath(names) throws InvalidOperation, ObjectDoesNotExist

Get the file this action logs to.

```
String[] getLogFilePath(
   String[] names
)
```

getLogFilePathByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the file this action logs to. This is a location specific function, any action will operate on the specified location.

```
String[] getLogFilePathByLocation(
   String location
   String[] names
)
```

getSOAPAdditional(names) throws InvalidOperation, ObjectDoesNotExist

Get the additional information to send with the SOAP alert call.

```
String[] getSOAPAdditional(
   String[] names
)
```

getSOAPAdditionalByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the additional information to send with the SOAP alert call. This is a location specific function, any action will operate on the specified location.

```
String[] getSOAPAdditionalByLocation(
   String location
   String[] names
)
```

getSOAPAuthentication(names) throws InvalidOperation, ObjectDoesNotExist

Gets the username used to log in with HTTP basic authentication. The actions specified must be of type 'soap'. Note that the password field is always returned as an empty string.

```
Alerting.Action.Login[] getSOAPAuthentication(
   String[] names
)
```

getSOAPAuthenticationByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Gets the username used to log in with HTTP basic authentication. The actions specified must be of type 'soap'. Note that the password field is always returned as an empty string. This is a location specific function, any action will operate on the specified location.

```
Alerting.Action.Login[] getSOAPAuthenticationByLocation(
   String location
```

```
    String[] names
)
```

getSOAPProxy(names) throws InvalidOperation, ObjectDoesNotExist

Get the server the SOAP event call will be made to for each of the specified SOAP events.

```
String[] getSOAPProxy(
    String[] names
)
```

getSOAPProxyByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the server the SOAP event call will be made to for each of the specified SOAP events. This is a location specific function, any action will operate on the specified location.

```
String[] getSOAPProxyByLocation(
    String location
    String[] names
)
```

getScriptArguments(names) throws InvalidOperation, ObjectDoesNotExist

Gets all arguments for the specified script actions. The actions specified must be of type 'program'.

```
Alerting.Action.Argument[][] getScriptArguments(
    String[] names
)
```

getScriptProgram(names) throws InvalidOperation, ObjectDoesNotExist

Get the program to run including its command line arguments. The actions specified must be of type 'program'.

```
String[] getScriptProgram(
    String[] names
)
```

getSyslogHost(names) throws InvalidOperation, ObjectDoesNotExist

Get the host to send syslog messages to (if empty, messages will be sent to localhost). The actions specified must be of type 'syslog'.

```
String[] getSyslogHost(
    String[] names
)
```

getSyslogHostByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the host to send syslog messages to (if empty, messages will be sent to localhost). The actions specified must be of type 'syslog'. This is a location specific function, any action will operate on the specified location.

```
String[] getSyslogHostByLocation(
   String location
   String[] names
)
```

getTimeout(names) throws InvalidOperation, ObjectDoesNotExist

Get how long an action has to run, in seconds (set to 0 disable timing out).

```
Unsigned Integer[] getTimeout(
   String[] names
)
```

getTimeoutByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get how long an action has to run, in seconds (set to 0 disable timing out). This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getTimeoutByLocation(
   String location
   String[] names
)
```

getTrapCommunity(names) throws InvalidOperation, ObjectDoesNotExist

Get the SNMP community string for the SNMP trap. The actions specified must be of type 'trap'.

```
String[] getTrapCommunity(
   String[] names
)
```

getTrapCommunityByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the SNMP community string for the SNMP trap. The actions specified must be of type 'trap'. This is a location specific function, any action will operate on the specified location.

```
String[] getTrapCommunityByLocation(
   String location
   String[] names
```

)

getTrapHost(names) throws InvalidOperation, ObjectDoesNotExist

Get the hostname or IPv4 address and optional port number that should receive the SNMP trap. The actions specified must be of type 'trap'.

```
String[] getTrapHost(
   String[] names
)
```

getTrapHostByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get the hostname or IPv4 address and optional port number that should receive the SNMP trap. The actions specified must be of type 'trap'. This is a location specific function, any action will operate on the specified location.

```
String[] getTrapHostByLocation(
   String location
   String[] names
)
```

getVerbose(names) throws InvalidOperation, ObjectDoesNotExist

Get if verbose logging is enabled for this action.

```
Boolean[] getVerbose(
   String[] names
)
```

getVerboseByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist

Get if verbose logging is enabled for this action. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getVerboseByLocation(
   String location
   String[] names
)
```

removeSOAPAuthentication(names) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Disables using HTTP basic authentication with the SOAP Call. The actions specified must be of type 'soap'.

```
void removeSOAPAuthentication(
   String[] names
)
```

removeSOAPAuthenticationByLocation(location, names) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Disables using HTTP basic authentication with the SOAP Call. The actions specified must be of type 'soap'. This is a location specific function, any action will operate on the specified location.

```
void removeSOAPAuthenticationByLocation(
   String location
   String[] names
)
```

removeScriptArguments(names, arguments) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Removes a set of arguments from the specified script actions. The actions specified must be of type 'program'.

```
void removeScriptArguments(
   String[] names
   String[][] arguments
)
```

renameAction(names, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidOperation

Rename each of the named actions.

```
void renameAction(
   String[] names
   String[] new_names
)
```

setEmailRecipients(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the address the alert emails are sent from.

```
void setEmailRecipients(
   String[] names
   String[] values
)
```

setEmailRecipientsByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the address the alert emails are sent from. This is a location specific function, any action will operate on the specified location.

```
void setEmailRecipientsByLocation(
   String location
   String[] names
   String[] values
)
```

setEmailSMTPServer(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the SMTP server used to send alert emails for the specified actions.

```
void setEmailSMTPServer(
   String[] names
   String[] values
)
```

setEmailSMTPServerByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the SMTP server used to send alert emails for the specified actions. This is a location specific function, any action will operate on the specified location.

```
void setEmailSMTPServerByLocation(
   String location
   String[] names
   String[] values
)
```

setEmailSender(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the specified email addresses to the recipient list for the specified actions.

```
void setEmailSender(
   String[] names
   String[] values
)
```

setEmailSenderByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the specified email addresses to the recipient list for the specified actions. This is a location specific function, any action will operate on the specified location.

```
void setEmailSenderByLocation(
   String location
   String[] names
   String[] values
)
```

setLogFilePath(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the file this action logs to.

```
void setLogFilePath(
   String[] names
   String[] values
)
```

setLogFilePathByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the file this action logs to. This is a location specific function, any action will operate on the specified location.

```
void setLogFilePathByLocation(
   String location
   String[] names
   String[] values
)
```

setSOAPAdditional(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the additional information to send with the SOAP alert call.

```
void setSOAPAdditional(
   String[] names
   String[] values
)
```

setSOAPAdditionalByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the additional information to send with the SOAP alert call. This is a location specific function, any action will operate on the specified location.

```
void setSOAPAdditionalByLocation(
   String location
   String[] names
   String[] values
)
```

setSOAPAuthentication(names, credentials) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Sets the username and password to use to log in with HTTP basic authentication. The actions specified must be of type 'soap'.

```
void setSOAPAuthentication(
   String[] names
   Alerting.Action.Login[] credentials
)
```

setSOAPAuthenticationByLocation(location, names, credentials) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Sets the username and password to use to log in with HTTP basic authentication. The actions specified must be of type 'soap'. This is a location specific function, any action will operate on the specified location.

```
void setSOAPAuthenticationByLocation(
   String location
   String[] names
   Alerting.Action.Login[] credentials
)
```

setSOAPProxy(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the server the SOAP event call will be made to for each of the specified SOAP events.

```
void setSOAPProxy(
   String[] names
   String[] values
)
```

setSOAPProxyByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the server the SOAP event call will be made to for each of the specified SOAP events. This is a location specific function, any action will operate on the specified location.

```
void setSOAPProxyByLocation(
   String location
   String[] names
   String[] values
)
```

setScriptProgram(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the program to run including its command line arguments. The actions specified must be of type 'program'.

```
void setScriptProgram(
   String[] names
   String[] values
)
```

setSyslogHost(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the host to send syslog messages to (if empty, messages will be sent to localhost). The actions specified must be of type 'syslog'.

```
void setSyslogHost(
   String[] names
   String[] values
)
```

setSyslogHostByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the host to send syslog messages to (if empty, messages will be sent to localhost). The actions specified must be of type 'syslog'. This is a location specific function, any action will operate on the specified location.

```
void setSyslogHostByLocation(
   String location
   String[] names
   String[] values
)
```

setTimeout(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set how long an action has to run, in seconds (set to 0 disable timing out).

```
void setTimeout(
   String[] names
   Unsigned Integer[] values
)
```

setTimeoutByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set how long an action has to run, in seconds (set to 0 disable timing out). This is a location specific function, any action will operate on the specified location.

```
void setTimeoutByLocation(
   String location
   String[] names
   Unsigned Integer[] values
)
```

setTrapCommunity(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the SNMP community string for the SNMP trap. The actions specified must be of type 'trap'.

```
void setTrapCommunity(
   String[] names
   String[] values
)
```

setTrapCommunityByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the SNMP community string for the SNMP trap. The actions specified must be of type 'trap'. This is a location specific function, any action will operate on the specified location.

```
void setTrapCommunityByLocation(
   String location
   String[] names
   String[] values
)
```

setTrapHost(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the hostname or IPv4 address and optional port number that should receive the SNMP trap. The actions specified must be of type 'trap'.

```
void setTrapHost(
   String[] names
   String[] values
)
```

setTrapHostByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set the hostname or IPv4 address and optional port number that should receive the SNMP trap. The actions specified must be of type 'trap'. This is a location specific function, any action will operate on the specified location.

```
void setTrapHostByLocation(
   String location
   String[] names
   String[] values
)
```

setVerbose(names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set if verbose logging is enabled for this action.

```
void setVerbose(
   String[] names
   Boolean[] values
)
```

setVerboseByLocation(location, names, values) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Set if verbose logging is enabled for this action. This is a location specific function, any action will operate on the specified location.

```
void setVerboseByLocation(
   String location
   String[] names
   Boolean[] values
)
```

testAction(names) throws ObjectDoesNotExist

Sends a test event to the named actions to confirm that they are working as expected.

```
void testAction(
    String[] names
)
```

updateScriptArguments(names, argument_names, new_arguments) throws InvalidOperation, ObjectDoesNotExist, InvalidInput, DeploymentError

Allows arguments for the the specified script actions to be changed. The actions specified must be of type 'program'.

```
void updateScriptArguments(
    String[] names
    String[][] argument_names
    Alerting.Action.Argument[][] new_arguments
)
```

uploadActionProgram(name, content) throws InvalidObjectName, DeploymentError

Uploads an action program, overwriting the file if it already exists.

```
void uploadActionProgram(
    String name
    Binary Data content
)
```

6.22.2 Structures

Alerting.Action.Argument

An argument that is added to the command line when the script is run

```
struct Alerting.Action.Argument {
    # The name of the argument.
    String name;

    # The value of the argument.
    String value;

    # A description of the argument.
    String description;
}
```

Alerting.Action.Login

An argument that is added to the command line when the script is run

```
struct Alerting.Action.Login {
    # The username for basic SOAP authentication
    String username;

    # The username for basic SOAP authentication
    String password;
}
```

6.22.3 Enumerations

Alerting.Action.Type

```
enum Alerting.Action.Type {
    # Sends e-mails to a set of e-mail addresses.
    email,

    # Reports event information to a remote server using the SOAP
    # protocol.
    soap,

    # Sends an SNMP message to a remote server.
    trap,

    # Writes a log line in the syslog.
    syslog,

    # Writes a log line in a named file.
    log,

    # Executes an external program.
    program
}
```

6.23 AlertCallback

URI: http://soap.zeus.com/zxtm/1.0/AlertCallback/

AlertCallback is a callback interface that can be implemented on a separate server to receive events via SOAP from the traffic manager. This interface is not implemented by traffic manager itself.

6.23.1 Methods

eventOccurred(zxtm, time, severity, primary_tag, tags, objects, description, additional, event_type)

This function is used by the traffic manager to report an event using a SOAP call. You can easily identify the event being reported using the primary_tag field, which is the event's unique identifier. The tags array is reserved for future use, and will be empty.

```
void eventOccurred(
    String zxtm
    Time time
    AlertCallback.Severity severity
    AlertCallback.Tag primary_tag
    AlertCallback.Tag[] tags
    AlertCallback.Object[] objects
    String description
    String additional
    String event_type
)
```

6.23.2 Structures

AlertCallback.Object

Information on an object that triggered this event.

```
struct AlertCallback.Object {
    # The type of the object
    AlertCallback.ObjectType type;

    # The name of the object.
    String name;
}
```

6.23.3 Enumerations

AlertCallback.ObjectType

```
enum AlertCallback.ObjectType {
    # An unexpected type
    Unknown,

    # Actions
    actions,

    # Authenticators
    auth,
```

```
# Bandwidth Classes

                tips,

                # Custom Events
                trafficscript,

                # Virtual Servers
                vservers,

                # Traffic Managers
```

```
        zxtms
    }
```

AlertCallback.Severity

```
enum AlertCallback.Severity {
    # Denial of Service Event
    DOS,

    # Fatal Error Event
    FATAL,

    # Information Event
    INFO,

    # Serious Error Event
    SERIOUS,

    # SSL Error Event
    SSL,

    # Warning Event
    WARN
}
```

AlertCallback.Tag

```
enum AlertCallback.Tag {
    # This tag is used to with emitting a custom event generated
    # with the TrafficScript function 'event.emit'. Look at the
    # object that came with the callback to see the name of the
    # custom event
    CustomEvent,

    # An unknown tag

6.24 System.AccessLogs

URI: `http://soap.zeus.com/zxtm/1.0/System/AccessLogs/`

The AccessLogs interfaces provide operations on saved virtual server access logs for a Zeus Appliance. This interface is only available on a Zeus Appliance and is deprecated; use the System.RequestLogs interface instead.

6.24.1 Methods

deleteAllVSAccessLogs() throws InvalidOperation

Delete all the access logs for all virtual servers.

```
   void deleteAllVSAccessLogs()
```

deleteVSAccessLog(logfiles) throws InvalidOperation, InvalidInput

Delete the specified access logs.

```
   void deleteVSAccessLog(
      String[] logfiles
   )
```

deleteVSAccessLogs(vservers) throws InvalidOperation

Delete the access logs for specific virtual servers.

```
   void deleteVSAccessLogs(
      String[] vservers
   )
```

getAllVSAccessLogs() throws InvalidOperation

Get the access logs for all virtual servers.

```
   System.AccessLogs.VSAccessLog[] getAllVSAccessLogs()
```

getVSAccessLogs(vservers) throws InvalidOperation

Get the access logs for specific virtual servers.

```
System.AccessLogs.VSAccessLog[][] getVSAccessLogs(
    String[] vservers
)
```

6.24.2 Structures

System.AccessLogs.VSAccessLog

This structure contains the information for each virtual server access log.

```
struct System.AccessLogs.VSAccessLog {
    # The log filename.
    String filename;

    # The virtual server for this logfile.
    String virtual_server;

    # The date this logfile was created.
    Time logdate;

    # The size (in bytes) of this logfile.
    Integer filesize;
}
```

6.25 System.Cache

URI: http://soap.zeus.com/zxtm/1.2/System/Cache/

The System.Cache interface provides information about the content cache for a machine. Using this interface, you can retrieve both individual cache entries and global cache data, delete all entries in the cache, delete entries matching wildcards or delete individual entries.

6.25.1 Methods

clearCacheContentItems(virtual_servers, protocols, hosts, items)

Delete individual items from the Web Cache. All input arguments are arrays of strings and only those items are deleted whose virtual server, protocol, host and path attribute match all the corresponding values for a given index into the arguments.

```
void clearCacheContentItems(
    String[] virtual_servers
```

```
    System.Cache.Protocol[] protocols
    String[] hosts
    String[] items
)
```

clearMatchingCacheContent(protocol, host_wildcard, path_wildcard)

Delete the Web Cache entries matching the input arguments.

```
void clearMatchingCacheContent(
    System.Cache.Protocol protocol
    String host_wildcard
    String path_wildcard
)
```

clearWebCache()

Clear all entries from the Web Cache for this machine.

```
void clearWebCache()
```

getCacheContent(protocol, host_wildcard, path_wildcard, max_entries)

Get information about the Web Cache entries matching the input arguments.

```
System.Cache.CacheContentInfo getCacheContent(
    System.Cache.Protocol protocol
    String host_wildcard
    String path_wildcard
    Integer max_entries
)
```

getGlobalCacheInfo()

Get the size of the Web Cache, the number of Web Cache entries and the percentage memory used by the Web Cache for this machine.

```
System.Cache.GlobalInfo getGlobalCacheInfo()
```

6.25.2 Structures

System.Cache.CacheContent

This structure contains the basic information about an individual cache entry for a machine.

```
struct System.Cache.CacheContent {
    # The virtual server hosting the entry.
    String virtual_server;
```

```
# The protocol of the entry: http or https.
System.Cache.Protocol protocol;

# The host name of the entry.
String host;

# The path of the entry.
String path;

# The time that the entry was last used.
Time time_used;

# The time that the entry expires.
Time time_expires;

# The number of hits for the entry.
Long hits;

# The number of variants of this entry in the cache.
Integer num_variants;

# The HTTP response code for this entry in the cache.
Integer response_code;

# The HTTP versions the entry is cached for.
String[] versions;

# The set of request-header fields that determine if the cache
# entry may be used for a particular request.
String[] varys;
}
```

System.Cache.CacheContentInfo

This structure contains the information about the cache content.

```
struct System.Cache.CacheContentInfo {
   # The total number of items matching the wildcards in a query.
   Integer number_matching_items;

   # The total size of the items matching the wildcards in a
   # query.
   Long size_matching_items;

   # The set of individual entries in the cache that matched the
   # query.
   System.Cache.CacheContent[] matching_items;
}
```

System.Cache.GlobalInfo

This structure contains the basic information about the content cache for a machine.

```
struct System.Cache.GlobalInfo {
    # The number of bytes of memory used by the cache.
    Long bytes_used;

    # The percentage of the cache used.
    Float percent_used;

    # The number of entries in the cache.
    Integer entries;

    # The number of times a request has tried to get a page from
    # the cache.
    Long num_lookups;

    # The number of times a request has successfully been served
    # from the cache.
    Long num_hits;
}
```

6.25.3 Enumerations

System.Cache.Protocol

This enumeration defines the possible protocols for cache entries.

```
enum System.Cache.Protocol {
    # The hypertext transfer protocol (port 80 by default).
    http,

    # The hypertext transfer protocol secure (port 443 by
    # default).
    https,

    # This special value can be used as wildcard to match both
    # http and https. It is never returned by the methods in this
    # interface.
    both
}
```

6.26 System.Connections

URI: http://soap.zeus.com/zxtm/1.0/System/Connections/

The System.Connections interface provides information about the current and recent connections for this machine. Using this interface you can retrieve a list of all connections.

6.26.1 Methods

getAllConnections()

Get a list of all connections, current and recent, for this machine.

```
System.Connections.Connection[] getAllConnections()
```

6.26.2 Structures

System.Connections.Connection

This structure contains the basic information about a Connection. It is used when retrieving the current and recent connections for a machine.

```
struct System.Connections.Connection {
    # The source IP address and port for connection.
    String from;

    # The local IP address and port for connection.
    String via;

    # The destination node for the connection.
    String to;

    # The connection state.
    System.Connections.ConnectionState state;

    # The virtual server handling the request.
    String vserver;

    # The rule being executed.
    String rule;

    # The pool being used.
    String pool;

    # The number of bytes that were received from the client.
    Integer bytes_in;

    # The number of bytes that were sent to the client.
    Integer bytes_out;

    # The length of time that the connection has been established,
    # in seconds.
    Integer time_est;

    # The length of time since receiving the last client data, in
    # seconds.
    Integer time_client;
```

```
                  # The length of time since receiving the last server data, in
                  # seconds.
                  Integer time_server;

                  # The number of times that the connection to the node has been
                  # retried.
                  Integer retries;

                  # The Service Level Monitoring class being used.
                  String slm_class;

                  # The Virtual Server Bandwidth class being used.
                  String vs_bwclass;

                  # The Pool Bandwidth class being used.
                  String pool_bwclass;

                  # The status code in the HTTP response.
                  String code;

                  # The host header/URL in the HTTP request.
                  String request;
              }
```

6.26.3 Enumerations

System.Connections.ConnectionState

This enumeration defines the possible states for a particular connection.

```
      enum System.Connections.ConnectionState {
          # Current connection: reading data from the client ('R').
          reading_from_client,

          # Current connection: writing data to the client ('W').
          writing_to_client,

          # Current connection: executing rules against client request
          # ('X').
          executing_rule,

          # Current connection: connecting to a node ('c').
          connecting_to_node,

          # Current connection: writing data to a node ('w').
          writing_to_node,

          # Current connection: reading data from a node ('r').
          reading_from_node,

          # Current connection: closing connection with client ('C').
```

```
        closing_client_connection,

        # Current connection: holding connection with client in
        # keepalive state ('K').
        holding_client_connection,

        # Recent connection that is no longer active.
        recent_connection
    }
```

6.27 System.LicenseKeys

URI: `http://soap.zeus.com/zxtm/1.0/System/LicenseKeys/`

The System.LicenseKeys interface provides license key information for this machine. Using this interface, you can add and delete license keys, and retrieve both the license key currently in use and a list of all existing license keys.

6.27.1 Methods

addLicenseKeys(license_texts) throws ObjectAlreadyExists, InvalidInput

Create and add each of the named license keys.

```
Integer[] addLicenseKeys(
    String[] license_texts
)
```

deleteLicenseKeys(serials) throws ObjectDoesNotExist

Delete each of the named license keys.

```
void deleteLicenseKeys(
    Integer[] serials
)
```

getAllLicenseKeys()

Get a list of all the serial numbers of the existing license keys.

```
Integer[] getAllLicenseKeys()
```

getCurrentLicenseKey()

Get the serial number of the license key currently being used by this machine.

```
Integer getCurrentLicenseKey()
```

getLicenseKeys(serials) throws ObjectDoesNotExist

For each of the named license keys, get the license key structure.

```
System.LicenseKeys.LicenseKey[] getLicenseKeys(
   Integer[] serials
)
```

getRawLicenseKeys(serials) throws ObjectDoesNotExist

For each of the named license keys, get the raw license key text.

```
String[] getRawLicenseKeys(
   Integer[] serials
)
```

6.27.2 Structures

System.LicenseKeys.LicenseKey

This structure contains the basic information for a license key. It is used when adding, deleting or retrieving license keys.

```
struct System.LicenseKeys.LicenseKey {
   # The name of the product the license is for.
   String product;

   # The traffic manager software version for this machine.
   String version;

   # The list of platforms that the software may run on.
   String[] platforms;

   # The maximum number of CPUs that the software may run on.
   # Note that this field may not exist for all license keys in
   # which case its value will be '0'.
   Integer maxcpus;

   # The IP addresses of the machines that the software may run
   # on. Note that this field may not exist for all license keys
   # in which case its value will be the empty array.
   String[] ip_address;

   # The MAC addresses of the machines that the software may run
   # on. Note that this field may not exist for all license keys
   # in which case its value will be the empty array.
   String[] mac_address;

   # The features that are supported by the license key.
   String[] features;
```

```
                # The maximum number of backends supported by the license key.
                # Note that this field may not exist for all license keys in
                # which case its value will be '0'.
                Integer max_backends;

                # Additional customer information for the license key. Note
                # that this field may not exist for all license keys in which
                # case its value will be "".
                String customer_info;

                # The customer ID for the license key. Note that this field
                # may not exist for all license keys in which case its value
                # will be "".
                String customer_id;

                # The serial number of the license key.
                Integer serial;

                # The time at which the license key will expire.
                Time expires;

                # The time at which the license key was issued.
                Time issued;

                # The time at which the support contract for the license key
                # expires. Note that this field is for future use so may not
                # exist for all license keys, in which case its value will be
                # equal to '01/01/1970 00:00:00'.
                Time maintenance;

                # The hardware serial number for the appliance with this
                # license key. Note that this field is only applicable to Zeus
                # Appliances and otherwise will have the value "".
                String hwserial;

                # The maximum cluster size supported by the license key. Note
                # that this field may not exist for all license keys in which
                # case its value will be equal to '0'.
                Integer cluster_size;
        }
```

6.28 System.Log

URI: `http://soap.zeus.com/zxtm/1.0/System/Log/`

The System.Log interface provides audit log and error log information for this machine. Using this interface, you can retrieve the error log as a string, get a list of individual entries in the audit log and clear the error log.

6.28.1 Methods

clearErrorLog()

Clear the error log for this machine.

```
void clearErrorLog()
```

getAuditLog()

Get a list of the most recent elements of the audit log for this machine.

```
System.Log.AuditItem[] getAuditLog()
```

getAuditLogLines(max_lines)

Get a maximum of max_lines lines of the audit log for this machine.

```
System.Log.AuditItem[] getAuditLogLines(
    Integer max_lines
)
```

getErrorLogLines(max_lines)

Get a maximum of max_lines lines of the error log for this machine as a string, if max_lines is 0 then 1024 lines are returned.

```
String getErrorLogLines(
    Integer max_lines
)
```

getErrorLogString()

Get the error log for this machine as a string.

```
String getErrorLogString()
```

6.28.2 Structures

System.Log.AccessDenied

This is the operation parameters structure for 'accessdenied' operations (user denied access). It is used when getting Audit Log data.

```
struct System.Log.AccessDenied {
    # The name of the host that was denied access.
    String host;
}
```

System.Log.AddAuthenticator

This is the operation parameters structure for 'addauth' operations (authenticator added). It is used when getting Audit Log data.

```
struct System.Log.AddAuthenticator {
    # The name of the authenticator that was added.
    String modauth;

    # The type of the authenticator that was added.
    String authtype;
}
```

System.Log.AddFile

This is the operation parameters structure for 'addfile' operations (file added). It is used when getting Audit Log data.

```
struct System.Log.AddFile {
    # The name of the object that was added.
    String file;
}
```

System.Log.AddGroup

This is the operation parameters structure for 'addgroup' operations (group added). It is used when getting Audit Log data.

```
struct System.Log.AddGroup {
    # The name of the group that was added.
    String modgroup;
}
```

System.Log.AddUser

This is the operation parameters structure for 'adduser' operations (user added). It is used when getting Audit Log data.

```
struct System.Log.AddUser {
    # The name of the user that was added.
    String moduser;

    # The name of the group that the user was added to.
    String modgroup;
}
```

System.Log.Adhoc

This is the operation parameters structure for 'adhoc' operations (a custom event). It is used when getting Audit Log data.

```
struct System.Log.Adhoc {
    # The custom text used to describe the event.
    String text;

    # The (optional) name of the object used in the event.
    String obj;
}
```

System.Log.AuditItem

This structure contains the information about an event in the Audit Log file. It is used when getting Audit Log information.

```
struct System.Log.AuditItem {
    # The date and time at which the event occurred.
    Time date;

    # The name of the user who caused the event.
    String user;

    # The group of the user who caused the event.
    String group;

    # The authenticator that authorised the user who caused the
    # event.
    String auth;

    # The IP address of the user.
    String ip;

    # The type of operation that occurred.
    System.Log.OperationType op_type;

    # The list of parameters used in the operation. This list is
    # required for all operations with the exception of
    # LoginFail/Logout/Timeout operations for which there are no
    # additional parameters.
    System.Log.OpParam op_params;
}
```

System.Log.CopyAuthenticator

This is the operation parameters structure for 'copyauth' operations (authenticator copied). It is used when getting Audit Log data.

```
struct System.Log.CopyAuthenticator {
```

```
# The name of the authenticator that was copied.
String oldauth;

# The name of the authenticator that was created.
String modauth;

# The authenticator type.
String authtype;
}
```

System.Log.CopyFile

This is the operation parameters structure for 'copyfile' operations (file copied). It is used when getting Audit Log data.

```
struct System.Log.CopyFile {
    # The name of the new object.
    String file;

    # The name of the object on which the new object is based.
    String oldfile;
}
```

System.Log.CopyGroup

This is the operation parameters structure for 'copygroup' operations (group copied). It is used when getting Audit Log data.

```
struct System.Log.CopyGroup {
    # The name of the new group.
    String modgroup;

    # The name of the group on which the new group is based.
    String oldgroup;
}
```

System.Log.DeleteAuthenticator

This is the operation parameters structure for 'delauth' operations (authenticator deleted). It is used when getting Audit Log data.

```
struct System.Log.DeleteAuthenticator {
    # The name of the authenticator that was deleted.
    String modauth;

    # The type of the authenticator that was deleted.
    String authtype;
}
```

System.Log.DeleteFile

This is the operation parameters structure for 'delfile' operations (file deleted). It is used when getting Audit Log data.

```
struct System.Log.DeleteFile {
    # The name of the object that was deleted.
    String file;
}
```

System.Log.DeleteGroup

This is the operation parameters structure for 'delgroup' operations (group deleted). It is used when getting Audit Log data.

```
struct System.Log.DeleteGroup {
    # The name of the group that was deleted.
    String modgroup;
}
```

System.Log.DeleteUser

This is the operation parameters structure for 'deluser' operations (user deleted). It is used when getting Audit Log data.

```
struct System.Log.DeleteUser {
    # The name of the user that was deleted.
    String moduser;
}
```

System.Log.Login

This is the operation parameters structure for 'login' operations (user logged in). It is used when getting Audit Log data.

```
struct System.Log.Login {
    # The type of login.
    String logintype;

    # The user's timeout effective for the login session.
    String timeout;
}
```

System.Log.LoginFail

This is the operation parameters structure for 'loginfail' operations (login attempt failed). It is used when getting Audit Log data.

```
struct System.Log.LoginFail {
    # The type of login attempted.
```

```
    String logintype;

    # The resource the login was attempting to access.
    String resource;
}
```

System.Log.ModifyFile

This is the operation parameters structure for 'filemod' operations (a file other than a config key was modified). It is used when getting Audit Log data.

```
struct System.Log.ModifyFile {
    # The name of the object that was modified.
    String file;
}
```

System.Log.ModifyKey

This is the operation parameters structure for 'keymod' operations (config key modified). It is used when getting Audit Log data.

```
struct System.Log.ModifyKey {
    # The name of the object in which the modified key exists.
    String file;

    # The name of the key that was modified.
    String key;

    # The old value of the key.
    String oldval;

    # The new value of the key.
    String value;
}
```

System.Log.ModifyRule

This is the operation parameters structure for 'rulemod' operations (rule modified). It is used when getting Audit Log data.

```
struct System.Log.ModifyRule {
    # The name of the rule that was modified.
    String file;
}
```

System.Log.ModifyUser

This is the operation parameters structure for 'usermod' operations (user modified). It is used when getting Audit Log data.

```
struct System.Log.ModifyUser {
    # The name of the user that was added.
    String moduser;
}
```

System.Log.NoAccessPermission

This is the operation parameters structure for 'noperm' operations (no access permission).
It is used when getting Audit Log data.

```
struct System.Log.NoAccessPermission {
    # The name of the UI section to which access was denied.
    String section;
}
```

System.Log.NoChangePermission

This is the operation parameters structure for 'nopostperm' operations (no permission to
change data). It is used when getting Audit Log data.

```
struct System.Log.NoChangePermission {
    # The name of the UI section to which permission was denied.
    String section;
}
```

System.Log.OpParam

This is the base type structure for operation parameters. It is used when getting Audit Log
data.

```
struct System.Log.OpParam {

}
```

System.Log.RemoveKey

This is the operation parameters structure for 'removekey' operations (remove a config
key). It is used when getting Audit Log data.

```
struct System.Log.RemoveKey {
    # The name of the object in which the removed key existed.
    String file;

    # The name of the key that was removed.
    String key;

    # The old value of the key.
    String oldval;
}
```

System.Log.RenameFile

This is the operation parameters structure for 'renfile' operations (file renamed). It is used when getting Audit Log data.

```
struct System.Log.RenameFile implements System.Log.OpParam {
   # The new name of the object.
   String file;

   # The old name of the object.
   String oldfile;
}
```

System.Log.StartVS

This is the operation parameters structure for 'startvs' operations (start a Virtual Server). It is used when getting Audit Log data.

```
struct System.Log.StartVS {
   # The name of the Virtual Server that was started.
   String vs;
}
```

System.Log.StopVS

This is the operation parameters structure for 'stopvs' operations (stop a Virtual Server). It is used when getting Audit Log data.

```
struct System.Log.StopVS {
   # The name of the Virtual Server that was stopped.
   String vs;
}
```

6.28.3 Enumerations

System.Log.OperationType

This enumeration defines the possible types of operations that may exist in the audit log.

```
enum System.Log.OperationType {
   # An AddFile operation occurs when a file is added. This
   # operation is caused by a user creating a new object such as
   # a Virtual Server, Pool, etc. It appears as an 'addfile'
   # operation in the Audit Log.
   AddFile,

   # A DeleteFile operation occurs when a file is deleted. This
   # operation is caused by a user deleting an existing object
```

```
                    # such as a Virtual Server, Pool, etc. It appears as a
                    # 'delfile' operation in the Audit Log.
                    DeleteFile,

                    # A RenameFile operation occurs when a file is renamed. This
                    # operation is caused by a user renaming an existing object
                    # such as a Virtual Server, Pool, etc. It appears as a
                    # 'renfile' operation in the Audit Log.
                    RenameFile,

                    # An AddGroup operation occurs when a new group of users is
                    # created. It appears as an 'addgroup' operation in the Audit
                    # Log.
                    AddGroup,

                    # A DeleteGroup operation occurs when a group of users is
                    # deleted. It appears as an 'delgroup' operation in the Audit
                    # Log.
                    DeleteGroup,

                    # A CopyGroup operation occurs when a user group is saved with
                    # a new group name. It appears as an 'copygroup' operation in
                    # the Audit Log.
                    CopyGroup,

                    # An AddUser operation occurs when a new user is added. It
                    # appears as an 'adduser' operation in the Audit Log.
                    AddUser,

                    # A DeleteUser operation occurs when an existing user is
                    # deleted. It appears as an 'deluser' operation in the Audit
                    # Log.
                    DeleteUser,

                    # A ModifyUser operation occurs when an existing user is
                    # modified. It appears as an 'usermod' operation in the Audit
                    # Log.
                    ModifyUser,

                    # A ModifyKey operation occurs when the value of a config file
                    # is modified. This operation is caused by a user changing the
                    # settings for an existing object such as a Virtual Server,
                    # Pool, etc. It appears as a 'keymod' operation in the Audit
                    # Log.
                    ModifyKey,

                    # A ModifyRule operation occurs when the contents of a rule
                    # are modified. This operation is caused by a user editing an
                    # existing rule. It appears as a 'rulemod' operation in the
                    # Audit Log.
                    ModifyRule,
```

```
# A ModifyFile operation occurs when the contents of a
# non-config file are modified. This differs from a ModifyKey
# operation in that ModifyFile operations are caused by the
# modification of non-config files which are not managed by
# the traffic manager, for example changing the settings of an
# SSL Certificate. It appears as a 'filemod' operation in the
# Audit Log.
ModifyFile,

# A CopyFile operation occurs when a file is copied. This
# operation is caused by the user saving an object as a new
# name, for example a Rule or an SSL Certificate. It appears
# as a 'copyfile' operation in the Audit Log.
CopyFile,

# An Adhoc operation represents a custom event which does not
# fit any of the other Operation Types. For example, it occurs
# when a user is adding or deleting a License Key or modifying
# the Security settings. It appears as an 'adhoc' operation
# the Audit Log.
Adhoc,

# An AccessDenied operation occurs when a user is denied
# access to the Admin Server due to access restrictions which
# are in place. It appears as an 'accessdenied' operation in
# the Audit Log.
AccessDenied,

# A NoAccessPermission operation occurs when a user is refused
# permission whist accessing a section of the Admin Server. It
# appears as a 'noperm' operation in the Audit Log.
NoAccessPermission,

# A NoChangePermission operation occurs when a user is refused
# permission to update data in a section of the Admin Server.
# It appears as a 'nopostperm' operation in the Audit Log.
NoChangePermission,

# A Login operation occurs when a user successfully logs on to
# the admin server. It appears as a 'login' operation in the
# Audit Log.
Login,

# A LoginFail operation occurs when a user tries and fails to
# log on to the admin server. This type of operation does not
# have any additional parameters to log therefore the
# 'op_params' field does not exist. It appears as a
# 'loginfail' operation in the Audit Log.
LoginFail,
```

```
            # A Logout operation occurs when a user successfully logs out
            # of the admin server. This type of operation does not have
            # any additional parameters to log therefore the 'op_params'
            # field does not exist. It appears as a 'logout' operation in
            # the Audit Log.
            Logout,

            # A Timeout operation occurs when a user session times out.
            # This type of operation does not have any additional
            # parameters to log therefore the 'op_params' field does not
            # exist. It appears as a 'timeout' operation in the Audit Log.
            Timeout,

            # A StartVS operation type occurs when a user starts an
            # existing virtual server. It appears as a 'startvs' operation
            # in the Audit Log.
            StartVS,

            # A StopVS operation type occurs when a user stops an existing
            # virtual server. It appears as a 'stopvs' operation in the
            # Audit Log.
            StopVS,

            # An AddAuthenticator operation type occurs when a new
            # authenticator is created. It appears as a 'addauth'
            # operation in the Audit Log.
            AddAuthenticator,

            # A DeleteAuthenticator operation type occurs when an existing
            # authenticator is deleted. It appears as a 'delauth'
            # operation in the Audit Log.
            DeleteAuthenticator,

            # A CopyAuthenticator operation type occurs when a new
            # authenticator is created by saving an existing authenticator
            # to a new name. It appears as a 'copyauth' operation in the
            # Audit Log.
            CopyAuthenticator,

            # A RemoveKey operation type occurs when a key is removed from
            # a config file, usually because a key is being made location
            # specific.
            RemoveKey,

            # A Synchronise operation type occurs when configuration is
            # replicated from one machine across the cluster, for example
            # in order to resolve a conflict arising from one machine
            # being unavailable at the time when a configuration change
            # was made.
            Synchronise
    }
```

6.29 System.MachineInfo

URI: `http://soap.zeus.com/zxtm/1.0/System/MachineInfo/`

The System.MachineInfo interface provides information about the IP addresses, MAC addresses and traffic manager software version for this machine.

6.29.1 Methods

getAllClusterMachines()

Gets all of the machines in this traffic manager's cluster.

```
System.MachineInfo.Machine[] getAllClusterMachines()
```

getIPAddresses()

Get a list of IP addresses for this machine.

```
String[] getIPAddresses()
```

getMACAddresses()

Get a list of MAC addresses for this machine.

```
String[] getMACAddresses()
```

getProductVersion()

Get the traffic manager software version for this machine.

```
String getProductVersion()
```

getTrafficManagerUptime()

Get the time (in seconds) that the traffic manager has been running for.

```
Unsigned Integer getTrafficManagerUptime()
```

getZeusHome()

Get the install location of the traffic manager software (ZEUSHOME).

```
String getZeusHome()
```

isIPv6Enabled()

Check whether IPv6 is enabled on this system and supported by the traffic manager

```
Boolean isIPv6Enabled()
```

6.29.2 Structures

System.MachineInfo.Machine

This structure contains information about a traffic manager in the cluster.

```
struct System.MachineInfo.Machine {
   # The hostname of this machine
   String hostname;

   # The IP address of this machine.
   String ipaddress;

   # The URL of the admin server for this traffic manager.
   String admin_server;

   # The install path of the traffic manager on this machine.
   String zeushome;
}
```

6.30 System.RequestLogs

URI: `http://soap.zeus.com/zxtm/1.0/System/RequestLogs/`

The RequestLogs interfaces provide operations on saved virtual server request logs for a Zeus Appliance. This interface is only available on a Zeus Appliance.

6.30.1 Methods

deleteAllVSRequestLogs() throws InvalidOperation

Delete all the request logs for all virtual servers.

```
void deleteAllVSRequestLogs()
```

deleteVSRequestLog(logfiles) throws InvalidInput, InvalidOperation

Delete the specified request logs.

```
void deleteVSRequestLog(
   String[] logfiles
)
```

deleteVSRequestLogs(vservers) throws InvalidOperation

Delete the request logs for specific virtual servers.

```
void deleteVSRequestLogs(
   String[] vservers
)
```

getAllVSRequestLogs() throws InvalidOperation

Get the request logs for all virtual servers.

```
System.RequestLogs.VSRequestLog[] getAllVSRequestLogs()
```

getVSRequestLogs(vservers) throws InvalidOperation

Get the request logs for specific virtual servers.

```
System.RequestLogs.VSRequestLog[][] getVSRequestLogs(
   String[] vservers
)
```

6.30.2 Structures

System.RequestLogs.VSRequestLog

This structure contains the information for each virtual server request log.

```
struct System.RequestLogs.VSRequestLog {
   # The log filename.
   String filename;

   # The virtual server for this logfile.
   String virtual_server;

   # The date this logfile was created.
   Time logdate;

   # The size (in bytes) of this logfile.
   Integer filesize;
}
```

6.31 System.Stats

URI: http://soap.zeus.com/zxtm/1.0/System/Stats/

The System.Stats interface retrieves statistical information about the system. This interface is essentially an implementation of part of the SNMP interface in SOAP.

6.31.1 Methods

getActionNumber()

The number of actions configured in the traffic manager.

```
Integer getActionNumber()
```

getActions()

Gets the list of Alerting Actions configured.

```
String[] getActions()
```

getActionsProcessed(names) throws InvalidInput, InvalidObjectName

Number of times this action has been processed, for each of the named Actions.

```
Integer[] getActionsProcessed(
    String[] names
)
```

getAspSessionCacheEntries()

The total number of ASP sessions stored in the cache.

```
Integer getAspSessionCacheEntries()
```

getAspSessionCacheEntriesMax()

The maximum number of ASP sessions in the cache.

```
Integer getAspSessionCacheEntriesMax()
```

getAspSessionCacheHitRate()

The percentage of ASP session lookups that succeeded.

```
Integer getAspSessionCacheHitRate()
```

getAspSessionCacheHits()

Number of times a ASP session entry has been successfully found in the cache.

```
Integer getAspSessionCacheHits()
```

getAspSessionCacheLookups()

Number of times a ASP session entry has been looked up in the cache.

```
Integer getAspSessionCacheLookups()
```

getAspSessionCacheMisses()

Number of times a ASP session entry has not been available in the cache.

```
Integer getAspSessionCacheMisses()
```

getAspSessionCacheOldest()

The age of the oldest ASP session in the cache (in seconds).

```
Integer getAspSessionCacheOldest()
```

getBandwidthClassBytesOut(names) throws InvalidInput, InvalidObjectName

Bytes output by connections assigned to this bandwidth class, for each of the named BandwidthClasses.

```
Long[] getBandwidthClassBytesOut(
    String[] names
)
```

getBandwidthClassGuarantee(names) throws InvalidInput, InvalidObjectName

Guaranteed bandwidth class limit (kbits/s). Currently unused, for each of the named BandwidthClasses.

```
Integer[] getBandwidthClassGuarantee(
    String[] names
)
```

getBandwidthClassMaximum(names) throws InvalidInput, InvalidObjectName

Maximum bandwidth class limit (kbits/s), for each of the named BandwidthClasses.

```
Integer[] getBandwidthClassMaximum(
    String[] names
)
```

getBandwidthClassNumber()

The number of bandwidth classes defined.

```
Integer getBandwidthClassNumber()
```

getBandwidthClasses()

Gets the list of Bandwidth Classes configured.

```
String[] getBandwidthClasses()
```

getCloudcredentialsClassNumber()

The number of cloud credentials sets defined.

```
Integer getCloudcredentialsClassNumber()
```

getCloudcredentialsNodeCreations(names) throws InvalidInput, InvalidObjectName

The number of instance creation API requests made with this set of cloud credentials, for each of the named Cloudcredentialses.

```
Integer[] getCloudcredentialsNodeCreations(
    String[] names
)
```

getCloudcredentialsNodeDeletions(names) throws InvalidInput, InvalidObjectName

The number of instance destruction API requests made with this set of cloud credentials, for each of the named Cloudcredentialses.

```
Integer[] getCloudcredentialsNodeDeletions(
    String[] names
)
```

getCloudcredentialsStatusRequests(names) throws InvalidInput, InvalidObjectName

The number of status API requests made with this set of cloud credentials, for each of the named Cloudcredentialses.

```
Integer[] getCloudcredentialsStatusRequests(
    String[] names
)
```

getCloudcredentialses()

Gets the list of Cloud Credentials configured.

```
String[] getCloudcredentialses()
```

getDataEntries()

Number of entries in the TrafficScript data.get()/set() storage.

```
Integer getDataEntries()
```

getDataMemoryUsage()

Number of bytes used in the TrafficScript data.get()/set() storage.

```
Integer getDataMemoryUsage()
```

getEventNumber()

The number of event configurations.

```
Integer getEventNumber()
```

getEvents()

Gets the list of Event Types configured.

```
String[] getEvents()
```

getEventsMatched(names) throws InvalidInput, InvalidObjectName

Number of times this event configuration has matched, for each of the named Events.

```
Integer[] getEventsMatched(
    String[] names
)
```

getEventsSeen()

Events seen by the traffic Manager's event handling process.

```
Integer getEventsSeen()
```

getGlbServiceDiscarded(names) throws InvalidInput, InvalidObjectName

Number of A records this GLB Service has discarded, for each of the named GlbServices.

```
Integer[] getGlbServiceDiscarded(
    String[] names
)
```

getGlbServiceNumber()

The number of GLB Services on this system.

```
Integer getGlbServiceNumber()
```

getGlbServiceResponses(names) throws InvalidInput, InvalidObjectName

Number of A records this GLB Service has altered, for each of the named GlbServices.

```
Integer[] getGlbServiceResponses(
    String[] names
)
```

getGlbServiceUnmodified(names) throws InvalidInput, InvalidObjectName

Number of A records this GLB Service has passed through unmodified, for each of the named GlbServices.

```
Integer[] getGlbServiceUnmodified(
    String[] names
)
```

getGlbServices()

Gets the list of GLB services configured.

```
String[] getGlbServices()
```

getInterfaceCollisions(names) throws InvalidInput, InvalidObjectName

The number of collisions reported by this interface, for each of the named Interfaces.

```
Integer[] getInterfaceCollisions(
    String[] names
)
```

getInterfaceNumber()

The number of network interfaces.

```
Integer getInterfaceNumber()
```

getInterfaceRxBytes(names) throws InvalidInput, InvalidObjectName

Bytes received by this interface, for each of the named Interfaces.

```
Long[] getInterfaceRxBytes(
    String[] names
```

```
)
```

getInterfaceRxErrors(names) throws InvalidInput, InvalidObjectName

The number of receive errors reported by this interface, for each of the named Interfaces.

```
Integer[] getInterfaceRxErrors(
   String[] names
)
```

getInterfaceRxPackets(names) throws InvalidInput, InvalidObjectName

The number of packets received by this interface, for each of the named Interfaces.

```
Integer[] getInterfaceRxPackets(
   String[] names
)
```

getInterfaceTxBytes(names) throws InvalidInput, InvalidObjectName

Bytes transmitted by this interface, for each of the named Interfaces.

```
Long[] getInterfaceTxBytes(
   String[] names
)
```

getInterfaceTxErrors(names) throws InvalidInput, InvalidObjectName

The number of transmit errors reported by this interface, for each of the named Interfaces.

```
Integer[] getInterfaceTxErrors(
   String[] names
)
```

getInterfaceTxPackets(names) throws InvalidInput, InvalidObjectName

The number of packets transmitted by this interface, for each of the named Interfaces.

```
Integer[] getInterfaceTxPackets(
   String[] names
)
```

getInterfaces()

Gets the list of Network Interfaces configured.

```
String[] getInterfaces()
```

getIpSessionCacheEntries()

The total number of IP sessions stored in the cache.

```
Integer getIpSessionCacheEntries()
```

getIpSessionCacheEntriesMax()

The maximum number of IP sessions in the cache.

```
Integer getIpSessionCacheEntriesMax()
```

getIpSessionCacheHitRate()

The percentage of IP session lookups that succeeded.

```
Integer getIpSessionCacheHitRate()
```

getIpSessionCacheHits()

Number of times a IP session entry has been successfully found in the cache.

```
Integer getIpSessionCacheHits()
```

getIpSessionCacheLookups()

Number of times a IP session entry has been looked up in the cache.

```
Integer getIpSessionCacheLookups()
```

getIpSessionCacheMisses()

Number of times a IP session entry has not been available in the cache.

```
Integer getIpSessionCacheMisses()
```

getIpSessionCacheOldest()

The age of the oldest IP session in the cache (in seconds).

```
Integer getIpSessionCacheOldest()
```

getJ2eeSessionCacheEntries()

The total number of J2EE sessions stored in the cache.

```
Integer getJ2eeSessionCacheEntries()
```

getJ2eeSessionCacheEntriesMax()

The maximum number of J2EE sessions in the cache.

```
Integer getJ2eeSessionCacheEntriesMax()
```

getJ2eeSessionCacheHitRate()

The percentage of J2EE session lookups that succeeded.

```
Integer getJ2eeSessionCacheHitRate()
```

getJ2eeSessionCacheHits()

Number of times a J2EE session entry has been successfully found in the cache.

```
Integer getJ2eeSessionCacheHits()
```

getJ2eeSessionCacheLookups()

Number of times a J2EE session entry has been looked up in the cache.

```
Integer getJ2eeSessionCacheLookups()
```

getJ2eeSessionCacheMisses()

Number of times a J2EE session entry has not been available in the cache.

```
Integer getJ2eeSessionCacheMisses()
```

getJ2eeSessionCacheOldest()

The age of the oldest J2EE session in the cache (in seconds).

```
Integer getJ2eeSessionCacheOldest()
```

getLicensekeyNumber()

The number of License keys.

```
Integer getLicensekeyNumber()
```

getListenIPBytesIn(listen_ip_addresses)

Bytes sent to this listening IP, for each of the specified ListenIPs.

```
Long[] getListenIPBytesIn(
    String[] listen_ip_addresses
)
```

getListenIPBytesOut(listen_ip_addresses)

Bytes sent from this listening IP, for each of the specified ListenIPs.

```
Long[] getListenIPBytesOut(
    String[] listen_ip_addresses
)
```

getListenIPCurrentConn(listen_ip_addresses)

TCP connections currently established to this listening IP, for each of the specified ListenIPs.

```
Integer[] getListenIPCurrentConn(
    String[] listen_ip_addresses
)
```

getListenIPMaxConn(listen_ip_addresses)

Maximum number of simultaneous TCP connections this listening IP has processed at any one time, for each of the specified ListenIPs.

```
Integer[] getListenIPMaxConn(
    String[] listen_ip_addresses
)
```

getListenIPTotalConn(listen_ip_addresses)

Requests sent to this listening IP, for each of the specified ListenIPs.

```
Integer[] getListenIPTotalConn(
    String[] listen_ip_addresses
)
```

getListenIPs()

Gets the list of all IP addresses that Virtual Servers are listening on.

```
String[] getListenIPs()
```

getLocationLoad(names) throws InvalidInput, InvalidObjectName

The mean load metric for this location, for each of the named Locations.

```
Integer[] getLocationLoad(
    String[] names
)
```

getLocationResponses(names) throws InvalidInput, InvalidObjectName

Number of A records that have been altered to point to this location, for each of the named Locations.

```
Integer[] getLocationResponses(
   String[] names
)
```

getLocations()

Gets the list of Locations configured.

```
String[] getLocations()
```

getMonitorNumber()

The number of Monitors.

```
Integer getMonitorNumber()
```

getNodeBytesFromNode(nodes) throws InvalidInput, InvalidObjectName

Bytes received from this node, for each of the specified Nodes.

```
Long[] getNodeBytesFromNode(
   System.Stats.Node[] nodes
)
```

getNodeBytesToNode(nodes) throws InvalidInput, InvalidObjectName

Bytes sent to this node, for each of the specified Nodes.

```
Long[] getNodeBytesToNode(
   System.Stats.Node[] nodes
)
```

getNodeCurrentConn(nodes) throws InvalidInput, InvalidObjectName

Current connections established to this node, includes idle connections, for each of the specified Nodes.

```
Integer[] getNodeCurrentConn(
   System.Stats.Node[] nodes
)
```

getNodeCurrentRequests(nodes) throws InvalidInput, InvalidObjectName

Active connections established to this node, does not include idle connections, for each of the specified Nodes.

```
Integer[] getNodeCurrentRequests(
    System.Stats.Node[] nodes
)
```

getNodeErrors(nodes) throws InvalidInput, InvalidObjectName

Number of timeouts, connection problems and other errors for this node, for each of the specified Nodes.

```
Integer[] getNodeErrors(
    System.Stats.Node[] nodes
)
```

getNodeFailures(nodes) throws InvalidInput, InvalidObjectName

Failures of this node, for each of the specified Nodes.

```
Integer[] getNodeFailures(
    System.Stats.Node[] nodes
)
```

getNodeIdleConns(nodes) throws InvalidInput, InvalidObjectName

Number of idle HTTP connections to this node, for each of the specified Nodes.

```
Integer[] getNodeIdleConns(
    System.Stats.Node[] nodes
)
```

getNodeNewConn(nodes) throws InvalidInput, InvalidObjectName

Requests that created a new connection to this node, for each of the specified Nodes.

```
Integer[] getNodeNewConn(
    System.Stats.Node[] nodes
)
```

getNodeNumber()

The number of nodes on this system (includes IPv4 and IPv6 nodes).

```
Integer getNodeNumber()
```

getNodePooledConn(nodes) throws InvalidInput, InvalidObjectName

Requests that reused an existing pooled/keepalive connection rather than creating a new TCP connection, for each of the specified Nodes.

```
Integer[] getNodePooledConn(
    System.Stats.Node[] nodes
)
```

getNodeResponseMax(nodes) throws InvalidInput, InvalidObjectName

Maximum response time (ms) in the last second for this node, for each of the specified Nodes.

```
Integer[] getNodeResponseMax(
    System.Stats.Node[] nodes
)
```

getNodeResponseMean(nodes) throws InvalidInput, InvalidObjectName

Mean response time (ms) in the last second for this node, for each of the specified Nodes.

```
Integer[] getNodeResponseMean(
    System.Stats.Node[] nodes
)
```

getNodeResponseMin(nodes) throws InvalidInput, InvalidObjectName

Minimum response time (ms) in the last second for this node, for each of the specified Nodes.

```
Integer[] getNodeResponseMin(
    System.Stats.Node[] nodes
)
```

getNodeState(nodes) throws InvalidInput, InvalidObjectName

The state of this node, for each of the specified Nodes.

```
System.Stats.NodeState[] getNodeState(
    System.Stats.Node[] nodes
)
```

getNodeTotalConn(nodes) throws InvalidInput, InvalidObjectName

Requests sent to this node, for each of the specified Nodes.

```
Integer[] getNodeTotalConn(
    System.Stats.Node[] nodes
```

)

getNodes()

Retrieves the list of available Nodes.

```
System.Stats.Node[] getNodes()
```

getNumIdleConnections()

Total number of idle HTTP connections to all nodes (used for future HTTP requests).

```
Integer getNumIdleConnections()
```

getNumberChildProcesses()

The number of traffic manager child processes.

```
Integer getNumberChildProcesses()
```

getNumberDNSACacheHits()

Requests for DNS A records resolved from the traffic manager's local cache.

```
Integer getNumberDNSACacheHits()
```

getNumberDNSARequests()

Requests for DNS A records (hostname->IP address) made by the traffic manager.

```
Integer getNumberDNSARequests()
```

getNumberDNSPTRCacheHits()

Requests for DNS PTR records resolved from the traffic manager's local cache.

```
Integer getNumberDNSPTRCacheHits()
```

getNumberDNSPTRRequests()

Requests for DNS PTR records (IP address->hostname) made by the traffic manager.

```
Integer getNumberDNSPTRRequests()
```

getNumberSNMPBadRequests()

Malformed SNMP requests received.

```
Integer getNumberSNMPBadRequests()
```

getNumberSNMPGetNextRequests()

SNMP GetNextRequests received.

```
Integer getNumberSNMPGetNextRequests()
```

getNumberSNMPGetRequests()

SNMP GetRequests received.

```
Integer getNumberSNMPGetRequests()
```

getNumberSNMPUnauthorisedRequests()

SNMP requests dropped due to access restrictions.

```
Integer getNumberSNMPUnauthorisedRequests()
```

getPerLocationServiceDraining(per_location_services) throws InvalidInput, InvalidObjectName

The draining state of this location for this GLB Service, for each of the specified PerLocationServices.

```
System.Stats.PerLocationServiceDraining[] getPerLocationServiceDraining(
    System.Stats.PerLocationService[] per_location_services
)
```

getPerLocationServiceFrontendState(per_location_services) throws InvalidInput, InvalidObjectName

The frontend state of this location for this GLB Service, for each of the specified PerLocationServices.

```
System.Stats.PerLocationServiceFrontendState[]
getPerLocationServiceFrontendState(
    System.Stats.PerLocationService[] per_location_services
)
```

getPerLocationServiceLoad(per_location_services) throws InvalidInput, InvalidObjectName

The load metric for this location for this GLB Service, for each of the specified PerLocationServices.

```
Integer[] getPerLocationServiceLoad(
```

```
        System.Stats.PerLocationService[] per_location_services
    )
```

getPerLocationServiceMonitorState(per_location_services) throws InvalidInput, InvalidObjectName

The monitor state of this location for this GLB Service, for each of the specified PerLocationServices.

```
    System.Stats.PerLocationServiceMonitorState[]
    getPerLocationServiceMonitorState(
        System.Stats.PerLocationService[] per_location_services
    )
```

getPerLocationServiceResponses(per_location_services) throws InvalidInput, InvalidObjectName

Number of A records that have been altered to point to this location for this GLB Service, for each of the specified PerLocationServices.

```
    Integer[] getPerLocationServiceResponses(
        System.Stats.PerLocationService[] per_location_services
    )
```

getPerLocationServiceState(per_location_services) throws InvalidInput, InvalidObjectName

The state of this location for this GLB Service, for each of the specified PerLocationServices.

```
    System.Stats.PerLocationServiceState[] getPerLocationServiceState(
        System.Stats.PerLocationService[] per_location_services
    )
```

getPerLocationServices()

Retrieves the list of available PerLocationServices.

```
    System.Stats.PerLocationService[] getPerLocationServices()
```

getPerNodeServiceLevelResponseMax(per_node_service_levels) throws InvalidInput, InvalidObjectName

Maximum response time (ms) in the last second for this SLM class to this node, for each of the specified PerNodeServiceLevels.

```
    Integer[] getPerNodeServiceLevelResponseMax(
        System.Stats.PerNodeServiceLevel[] per_node_service_levels
```

)

getPerNodeServiceLevelResponseMean(per_node_service_levels) throws InvalidInput, InvalidObjectName

Mean response time (ms) in the last second for this SLM class to this node, for each of the specified PerNodeServiceLevels.

```
Integer[] getPerNodeServiceLevelResponseMean(
    System.Stats.PerNodeServiceLevel[] per_node_service_levels
)
```

getPerNodeServiceLevelResponseMin(per_node_service_levels) throws InvalidInput, InvalidObjectName

Minimum response time (ms) in the last second for this SLM class to this node, for each of the specified PerNodeServiceLevels.

```
Integer[] getPerNodeServiceLevelResponseMin(
    System.Stats.PerNodeServiceLevel[] per_node_service_levels
)
```

getPerNodeServiceLevelTotalConn(per_node_service_levels) throws InvalidInput, InvalidObjectName

Requests handled by this SLM class to this node, for each of the specified PerNodeServiceLevels.

```
Integer[] getPerNodeServiceLevelTotalConn(
    System.Stats.PerNodeServiceLevel[] per_node_service_levels
)
```

getPerNodeServiceLevelTotalNonConf(per_node_service_levels) throws InvalidInput, InvalidObjectName

Non-conforming requests handled by this SLM class to this node, for each of the specified PerNodeServiceLevels.

```
Integer[] getPerNodeServiceLevelTotalNonConf(
    System.Stats.PerNodeServiceLevel[] per_node_service_levels
)
```

getPerNodeServiceLevels()

Retrieves the list of available PerNodeServiceLevels.

```
System.Stats.PerNodeServiceLevel[] getPerNodeServiceLevels()
```

getPerPoolNodeBytesFromNode(per_pool_nodes) throws InvalidInput, InvalidObjectName

Bytes received from this node, for each of the specified PerPoolNodes.

```
Long[] getPerPoolNodeBytesFromNode(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeBytesToNode(per_pool_nodes) throws InvalidInput, InvalidObjectName

Bytes sent to this node, for each of the specified PerPoolNodes.

```
Long[] getPerPoolNodeBytesToNode(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeCurrentConn(per_pool_nodes) throws InvalidInput, InvalidObjectName

Current connections established to a node, includes idle connections, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeCurrentConn(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeCurrentRequests(per_pool_nodes) throws InvalidInput, InvalidObjectName

Active connections established to this node, does not include idle connections, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeCurrentRequests(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeErrors(per_pool_nodes) throws InvalidInput, InvalidObjectName

Number of timeouts, connection problems and other errors for this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeErrors(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeFailures(per_pool_nodes) throws InvalidInput, InvalidObjectName

Failures of this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeFailures(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeIdleConns(per_pool_nodes) throws InvalidInput, InvalidObjectName

Number of idle HTTP connections to this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeIdleConns(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeNewConn(per_pool_nodes) throws InvalidInput, InvalidObjectName

Requests that created a new connection to this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeNewConn(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeNumber()

The number of nodes on this system.

```
Integer getPerPoolNodeNumber()
```

getPerPoolNodePooledConn(per_pool_nodes) throws InvalidInput, InvalidObjectName

Requests that reused an existing pooled/keepalive connection rather than creating a new TCP connection, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodePooledConn(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeResponseMax(per_pool_nodes) throws InvalidInput, InvalidObjectName

Maximum response time (ms) in the last second for this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeResponseMax(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeResponseMean(per_pool_nodes) throws InvalidInput, InvalidObjectName

Mean response time (ms) in the last second for this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeResponseMean(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeResponseMin(per_pool_nodes) throws InvalidInput, InvalidObjectName

Minimum response time (ms) in the last second for this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeResponseMin(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeState(per_pool_nodes) throws InvalidInput, InvalidObjectName

The state of this node, for each of the specified PerPoolNodes.

```
System.Stats.PerPoolNodeState[] getPerPoolNodeState(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodeTotalConn(per_pool_nodes) throws InvalidInput, InvalidObjectName

Requests sent to this node, for each of the specified PerPoolNodes.

```
Integer[] getPerPoolNodeTotalConn(
    System.Stats.PerPoolNode[] per_pool_nodes
)
```

getPerPoolNodes()

Retrieves the list of available PerPoolNodes.

```
System.Stats.PerPoolNode[] getPerPoolNodes()
```

getPoolAlgorithm(names) throws InvalidInput, InvalidObjectName

The load-balancing algorithm the pool uses, for each of the named Pools.

```
System.Stats.PoolAlgorithm[] getPoolAlgorithm(
    String[] names
)
```

getPoolBytesIn(names) throws InvalidInput, InvalidObjectName

Bytes received by this pool from nodes, for each of the named Pools.

```
Long[] getPoolBytesIn(
    String[] names
)
```

getPoolBytesOut(names) throws InvalidInput, InvalidObjectName

Bytes sent by this pool to nodes, for each of the named Pools.

```
Long[] getPoolBytesOut(
    String[] names
)
```

getPoolConnsQueued(names)

Total connections currently queued to this pool, for each of the named Pools.

```
Integer[] getPoolConnsQueued(
    String[] names
)
```

getPoolDisabled(names) throws InvalidInput, InvalidObjectName

The number of nodes in this pool that are disabled, for each of the named Pools.

```
Integer[] getPoolDisabled(
    String[] names
)
```

getPoolDraining(names) throws InvalidInput, InvalidObjectName

The number of nodes in this pool which are draining, for each of the named Pools.

```
Integer[] getPoolDraining(
    String[] names
)
```

getPoolMaxQueueTime(names)

Maximum time a connection was queued for, over the last second, for each of the named Pools.

```
Integer[] getPoolMaxQueueTime(
    String[] names
)
```

getPoolMeanQueueTime(names)

Mean time a connection was queued for, over the last second, for each of the named Pools.

```
Integer[] getPoolMeanQueueTime(
    String[] names
)
```

getPoolMinQueueTime(names)

Minimum time a connection was queued for, over the last second, for each of the named Pools.

```
Integer[] getPoolMinQueueTime(
    String[] names
)
```

getPoolNodes(names) throws InvalidInput, InvalidObjectName

The number of nodes registered with this pool, for each of the named Pools.

```
Integer[] getPoolNodes(
    String[] names
)
```

getPoolNumber()

The number of pools on this system.

```
Integer getPoolNumber()
```

getPoolPersistence(names) throws InvalidInput, InvalidObjectName

The session persistence method this pool uses, for each of the named Pools.

```
System.Stats.PoolPersistence[] getPoolPersistence(
   String[] names
)
```

getPoolQueueTimeouts(names)

Total connections that timed-out while queued, for each of the named Pools.

```
Integer[] getPoolQueueTimeouts(
   String[] names
)
```

getPoolSessionMigrated(names) throws InvalidInput, InvalidObjectName

Sessions migrated to a new node because the desired node was unavailable, for each of the named Pools.

```
Integer[] getPoolSessionMigrated(
   String[] names
)
```

getPoolState(names) throws InvalidInput, InvalidObjectName

The state of this pool, for each of the named Pools.

```
System.Stats.PoolState[] getPoolState(
   String[] names
)
```

getPoolTotalConn(names) throws InvalidInput, InvalidObjectName

Requests sent to this pool, for each of the named Pools.

```
Integer[] getPoolTotalConn(
   String[] names
)
```

getPools()

Gets the list of Pools configured.

```
String[] getPools()
```

getRateClassConnsEntered(names) throws InvalidInput, InvalidObjectName

Connections that have entered the rate class and have been queued, for each of the named RateClasses.

```
Integer[] getRateClassConnsEntered(
    String[] names
)
```

getRateClassConnsLeft(names) throws InvalidInput, InvalidObjectName

Connections that have left the rate class, for each of the named RateClasses.

```
Integer[] getRateClassConnsLeft(
    String[] names
)
```

getRateClassCurrentRate(names) throws InvalidInput, InvalidObjectName

The average rate that requests are passing through this rate class, for each of the named RateClasses.

```
Integer[] getRateClassCurrentRate(
    String[] names
)
```

getRateClassDropped(names) throws InvalidInput, InvalidObjectName

Requests dropped from this rate class without being processed (e.g. timeouts), for each of the named RateClasses.

```
Integer[] getRateClassDropped(
    String[] names
)
```

getRateClassMaxRatePerMin(names) throws InvalidInput, InvalidObjectName

The maximum rate that requests may pass through this rate class (requests/min), for each of the named RateClasses.

```
Integer[] getRateClassMaxRatePerMin(
    String[] names
)
```

getRateClassMaxRatePerSec(names) throws InvalidInput, InvalidObjectName

The maximum rate that requests may pass through this rate class (requests/sec), for each of the named RateClasses.

```
Integer[] getRateClassMaxRatePerSec(
    String[] names
)
```

getRateClassNumber()

The number of rate classes defined.

```
Integer getRateClassNumber()
```

getRateClassQueueLength(names) throws InvalidInput, InvalidObjectName

The current number of requests queued by this rate class, for each of the named RateClasses.

```
Integer[] getRateClassQueueLength(
    String[] names
)
```

getRateClasses()

Gets the list of Rate Classes configured.

```
String[] getRateClasses()
```

getRuleAborts(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has aborted, for each of the named Rules.

```
Integer[] getRuleAborts(
    String[] names
)
```

getRuleDiscards(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has discarded the connection, for each of the named Rules.

```
Integer[] getRuleDiscards(
    String[] names
)
```

getRuleExecutions(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has been executed, for each of the named Rules.

```
Integer[] getRuleExecutions(
    String[] names
)
```

getRuleNumber()

The number of TrafficScript rules.

```
Integer getRuleNumber()
```

getRulePoolSelect(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has selected a pool to use, for each of the named Rules.

```
Integer[] getRulePoolSelect(
    String[] names
)
```

getRuleResponds(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has responded directly to the client, for each of the named Rules.

```
Integer[] getRuleResponds(
    String[] names
)
```

getRuleRetries(names) throws InvalidInput, InvalidObjectName

Number of times this TrafficScript rule has forced the request to be retried, for each of the named Rules.

```
Integer[] getRuleRetries(
    String[] names
)
```

getRules()

Gets the list of Rules configured.

```
String[] getRules()
```

getServiceLevelConforming(names) throws InvalidInput, InvalidObjectName

Percentage of requests associated with this SLM class that are conforming, for each of the named ServiceLevels.

```
Integer[] getServiceLevelConforming(
    String[] names
)
```

getServiceLevelCurrentConns(names) throws InvalidInput, InvalidObjectName

The number of connections currently associated with this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelCurrentConns(
    String[] names
)
```

getServiceLevelIsOK(names) throws InvalidInput, InvalidObjectName

Indicates if this SLM class is currently conforming, for each of the named ServiceLevels.

```
System.Stats.ServiceLevelIsOK[] getServiceLevelIsOK(
    String[] names
)
```

getServiceLevelNumber()

The number of SLM classes defined.

```
Integer getServiceLevelNumber()
```

getServiceLevelResponseMax(names) throws InvalidInput, InvalidObjectName

Maximum response time (ms) in the last second for this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelResponseMax(
    String[] names
)
```

getServiceLevelResponseMean(names) throws InvalidInput, InvalidObjectName

Mean response time (ms) in the last second for this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelResponseMean(
    String[] names
)
```

getServiceLevelResponseMin(names) throws InvalidInput, InvalidObjectName

Minimum response time (ms) in the last second for this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelResponseMin(
    String[] names
)
```

getServiceLevelTotalConn(names) throws InvalidInput, InvalidObjectName

Requests handled by this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelTotalConn(
   String[] names
)
```

getServiceLevelTotalNonConf(names) throws InvalidInput, InvalidObjectName

Non-conforming requests handled by this SLM class, for each of the named ServiceLevels.

```
Integer[] getServiceLevelTotalNonConf(
   String[] names
)
```

getServiceLevels()

Gets the list of Service Level Monitoring classes configured.

```
String[] getServiceLevels()
```

getServiceProtLastRefusalTime(names) throws InvalidInput, InvalidObjectName

The time (in hundredths of a second) since this service protection class last refused a connection (this value will wrap if no connections are refused in more than 497 days), for each of the named ServiceProts.

```
Integer[] getServiceProtLastRefusalTime(
   String[] names
)
```

getServiceProtNumber()

The number of service protection classes defined.

```
Integer getServiceProtNumber()
```

getServiceProtRefusalBinary(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the request contained disallowed binary content, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalBinary(
   String[] names
)
```

getServiceProtRefusalConc10IP(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the top 10 source IP addresses issued too many concurrent connections, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalConc10IP(
    String[] names
)
```

getServiceProtRefusalConc1IP(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the source IP address issued too many concurrent connections, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalConc1IP(
    String[] names
)
```

getServiceProtRefusalConnRate(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the source IP address issued too many connections within 60 seconds, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalConnRate(
    String[] names
)
```

getServiceProtRefusalIP(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the source IP address was banned, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalIP(
    String[] names
)
```

getServiceProtRefusalRFC2396(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the HTTP request was not RFC 2396 compliant, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalRFC2396(
    String[] names
)
```

getServiceProtRefusalSize(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class because the request was larger than the defined limits allowed, for each of the named ServiceProts.

```
Integer[] getServiceProtRefusalSize(
   String[] names
)
```

getServiceProtTotalRefusal(names) throws InvalidInput, InvalidObjectName

Connections refused by this service protection class, for each of the named ServiceProts.

```
Integer[] getServiceProtTotalRefusal(
   String[] names
)
```

getServiceProts()

Gets the list of Service Protection Classes configured.

```
String[] getServiceProts()
```

getSslCacheEntries()

The total number of SSL sessions stored in the server cache.

```
Integer getSslCacheEntries()
```

getSslCacheEntriesMax()

The maximum number of SSL entries in the server cache.

```
Integer getSslCacheEntriesMax()
```

getSslCacheHitRate()

The percentage of SSL server cache lookups that succeeded.

```
Integer getSslCacheHitRate()
```

getSslCacheHits()

Number of times a SSL entry has been successfully found in the server cache.

```
Integer getSslCacheHits()
```

getSslCacheLookups()

Number of times a SSL entry has been looked up in the server cache.

```
Integer getSslCacheLookups()
```

getSslCacheMisses()

Number of times a SSL entry has not been available in the server cache.

```
Integer getSslCacheMisses()
```

getSslCacheOldest()

The age of the oldest SSL session in the server cache (in seconds).

```
Integer getSslCacheOldest()
```

getSslCipher3DESDecrypts()

Bytes decrypted with 3DES.

```
Integer getSslCipher3DESDecrypts()
```

getSslCipher3DESEncrypts()

Bytes encrypted with 3DES.

```
Integer getSslCipher3DESEncrypts()
```

getSslCipherAESDecrypts()

Bytes decrypted with AES.

```
Integer getSslCipherAESDecrypts()
```

getSslCipherAESEncrypts()

Bytes encrypted with AES.

```
Integer getSslCipherAESEncrypts()
```

getSslCipherDESDecrypts()

Bytes decrypted with DES.

```
Integer getSslCipherDESDecrypts()
```

getSslCipherDESEncrypts()

Bytes encrypted with DES.

```
Integer getSslCipherDESEncrypts()
```

getSslCipherDecrypts()

Bytes decrypted with a symmetric cipher.

```
Integer getSslCipherDecrypts()
```

getSslCipherEncrypts()

Bytes encrypted with a symmetric cipher.

```
Integer getSslCipherEncrypts()
```

getSslCipherRC4Decrypts()

Bytes decrypted with RC4.

```
Integer getSslCipherRC4Decrypts()
```

getSslCipherRC4Encrypts()

Bytes encrypted with RC4.

```
Integer getSslCipherRC4Encrypts()
```

getSslCipherRSADecrypts()

Number of RSA decrypts.

```
Integer getSslCipherRSADecrypts()
```

getSslCipherRSADecryptsExternal()

Number of external RSA decrypts.

```
Integer getSslCipherRSADecryptsExternal()
```

getSslCipherRSAEncrypts()

Number of RSA encrypts.

```
Integer getSslCipherRSAEncrypts()
```

getSslCipherRSAEncryptsExternal()

Number of external RSA encrypts.

```
Integer getSslCipherRSAEncryptsExternal()
```

getSslClientCertExpired()

Number of times a client certificate has expired.

```
Integer getSslClientCertExpired()
```

getSslClientCertInvalid()

Number of times a client certificate was invalid.

```
Integer getSslClientCertInvalid()
```

getSslClientCertNotSent()

Number of times a client certificate was required but not supplied.

```
Integer getSslClientCertNotSent()
```

getSslClientCertRevoked()

Number of times a client certificate was revoked.

```
Integer getSslClientCertRevoked()
```

getSslConnections()

Number of SSL connections negotiated.

```
Integer getSslConnections()
```

getSslHandshakeSSLv2()

Number of SSLv2 handshakes.

```
Integer getSslHandshakeSSLv2()
```

getSslHandshakeSSLv3()

Number of SSLv3 handshakes.

```
Integer getSslHandshakeSSLv3()
```

getSslHandshakeTLSv1()

Number of TLSv1.0 handshakes.

```
Integer getSslHandshakeTLSv1()
```

getSslHandshakeTLSv11()

Number of TLSv1.1 handshakes.

```
Integer getSslHandshakeTLSv11()
```

getSslSessionCacheEntries()

The total number of SSL session persistence entries stored in the cache.

```
Integer getSslSessionCacheEntries()
```

getSslSessionCacheEntriesMax()

The maximum number of SSL session persistence entries in the cache.

```
Integer getSslSessionCacheEntriesMax()
```

getSslSessionCacheHitRate()

The percentage of SSL session persistence lookups that succeeded.

```
Integer getSslSessionCacheHitRate()
```

getSslSessionCacheHits()

Number of times a SSL session persistence entry has been successfully found in the cache.

```
Integer getSslSessionCacheHits()
```

getSslSessionCacheLookups()

Number of times a SSL session persistence entry has been looked up in the cache.

```
Integer getSslSessionCacheLookups()
```

getSslSessionCacheMisses()

Number of times a SSL session persistence entry has not been available in the cache.

```
Integer getSslSessionCacheMisses()
```

getSslSessionCacheOldest()

The age of the oldest SSL session in the cache (in seconds).

```
Integer getSslSessionCacheOldest()
```

getSslSessionIDDiskCacheHit()

Number of times the SSL session id was found in the disk cache and reused (deprecated, will always return 0).

```
Integer getSslSessionIDDiskCacheHit()
```

getSslSessionIDDiskCacheMiss()

Number of times the SSL session id was not found in the disk cache (deprecated, will always return 0).

```
Integer getSslSessionIDDiskCacheMiss()
```

getSslSessionIDMemCacheHit()

Number of times the SSL session id was found in the cache and reused.

```
Integer getSslSessionIDMemCacheHit()
```

getSslSessionIDMemCacheMiss()

Number of times the SSL session id was not found in the cache.

```
Integer getSslSessionIDMemCacheMiss()
```

getSysCPUBusyPercent()

Percentage of time that the CPUs are busy.

```
Integer getSysCPUBusyPercent()
```

getSysCPUIdlePercent()

Percentage of time that the CPUs are idle.

```
Integer getSysCPUIdlePercent()
```

getSysCPUSystemBusyPercent()

Percentage of time that the CPUs are busy running system code.

```
Integer getSysCPUSystemBusyPercent()
```

getSysCPUUserBusyPercent()

Percentage of time that the CPUs are busy running user-space code.

```
Integer getSysCPUUserBusyPercent()
```

getSysFDsFree()

Number of free file descriptors.

```
Integer getSysFDsFree()
```

getSysMemBuffered()

Buffer memory (MBytes).

```
Integer getSysMemBuffered()
```

getSysMemFree()

Free memory (MBytes).

```
Integer getSysMemFree()
```

getSysMemInUse()

Memory used (MBytes).

```
Integer getSysMemInUse()
```

getSysMemSwapTotal()

Total swap space (MBytes).

```
Integer getSysMemSwapTotal()
```

getSysMemSwapped()

Amount of swap space in use (MBytes).

```
Integer getSysMemSwapped()
```

getSysMemTotal()

Total memory (MBytes).

```
Integer getSysMemTotal()
```

getTimeLastConfigUpdate()

The time (in hundredths of a second) since the configuration of traffic manager was updated (this value will wrap if no configuration changes are made for 497 days).

```
Integer getTimeLastConfigUpdate()
```

getTotalBackendServerErrors()

Total errors returned from the backend servers.

```
Integer getTotalBackendServerErrors()
```

getTotalBadDNSPackets()

Total number of malformed DNS response packets encountered from the backend servers.

```
Integer getTotalBadDNSPackets()
```

getTotalBytesIn()

Bytes received by the traffic manager from clients.

```
Long getTotalBytesIn()
```

getTotalBytesOut()

Bytes sent by the traffic manager to clients.

```
Long getTotalBytesOut()
```

getTotalConn()

Total number of TCP connections received.

```
Integer getTotalConn()
```

getTotalCurrentConn()

Number of TCP connections currently established.

```
Integer getTotalCurrentConn()
```

getTotalDNSResponses()

Total number of DNS response packets handled.

```
Integer getTotalDNSResponses()
```

getTotalRequests()

Total number of TCP requests recieved.

```
Integer getTotalRequests()
```

getTotalTransactions()

Total number of TCP requests being processed, after applying TPS limits.

```
Integer getTotalTransactions()
```

getTrafficIPARPMessage()

Number of ARP messages sent for raised Traffic IP Addresses.

```
Integer getTrafficIPARPMessage()
```

getTrafficIPGatewayPingRequests()

Number of ping requests sent to the gateway machine.

```
Integer getTrafficIPGatewayPingRequests()
```

getTrafficIPGatewayPingResponses()

Number of ping responses received from the gateway machine.

```
Integer getTrafficIPGatewayPingResponses()
```

getTrafficIPNodePingRequests()

Number of ping requests sent to the backend nodes.

```
Integer getTrafficIPNodePingRequests()
```

getTrafficIPNodePingResponses()

Number of ping responses received from the backend nodes.

```
Integer getTrafficIPNodePingResponses()
```

getTrafficIPNumber()

The number of traffic IP addresses on this system (includes IPv4 and IPv6 addresses).

```
Integer getTrafficIPNumber()
```

getTrafficIPNumberRaised()

The number of traffic IP addresses currently raised on this system (includes IPv4 and IPv6 addresses).

```
Integer getTrafficIPNumberRaised()
```

getTrafficIPPingResponseErrors()

Number of ping response errors.

```
Integer getTrafficIPPingResponseErrors()
```

getTrafficIPState(traffic_ip_addresses) throws InvalidInput, InvalidObjectName

Whether this traffic IP address is currently being hosted by this traffic manager, for each of the specified TrafficIPs.

```
System.Stats.TrafficIPState[] getTrafficIPState(
    String[] traffic_ip_addresses
)
```

getTrafficIPTime(traffic_ip_addresses) throws InvalidInput, InvalidObjectName

The time (in hundredths of a second) since trafficIPState last changed (this value will wrap if the state hasn't changed for 497 days), for each of the specified TrafficIPs.

```
Integer[] getTrafficIPTime(
    String[] traffic_ip_addresses
)
```

getTrafficIPs()

Gets the list of Traffic IP addresses configured.

```
String[] getTrafficIPs()
```

getUniSessionCacheEntries()

The total number of universal sessions stored in the cache.

```
Integer getUniSessionCacheEntries()
```

getUniSessionCacheEntriesMax()

The maximum number of universal sessions in the cache.

```
Integer getUniSessionCacheEntriesMax()
```

getUniSessionCacheHitRate()

The percentage of universal session lookups that succeeded.

```
Integer getUniSessionCacheHitRate()
```

getUniSessionCacheHits()

Number of times a universal session entry has been successfully found in the cache.

```
Integer getUniSessionCacheHits()
```

getUniSessionCacheLookups()

Number of times a universal session entry has been looked up in the cache.

```
Integer getUniSessionCacheLookups()
```

getUniSessionCacheMisses()

Number of times a universal session entry has not been available in the cache.

```
Integer getUniSessionCacheMisses()
```

getUniSessionCacheOldest()

The age of the oldest universal session in the cache (in seconds).

```
Integer getUniSessionCacheOldest()
```

getUpTime()

The time (in hundredths of a second) that Zeus software has been operational for (this value will wrap if it has been running for more than 497 days).

```
Integer getUpTime()
```

getUserCounterNumber()

The number of user defined counters.

```
Integer getUserCounterNumber()
```

getUserCounterValue(names) throws InvalidInput, InvalidObjectName

The value of the user counter, for each of the named UserCounters.

```
Integer[] getUserCounterValue(
    String[] names
)
```

getUserCounters()

Gets the list of User counters configured.

```
String[] getUserCounters()
```

getVirtualserverBytesIn(names) throws InvalidInput, InvalidObjectName

Bytes received by this virtual server from clients, for each of the named Virtualservers.

```
Long[] getVirtualserverBytesIn(
    String[] names
)
```

getVirtualserverBytesOut(names) throws InvalidInput, InvalidObjectName

Bytes sent by this virtual server to clients, for each of the named Virtualservers.

```
Long[] getVirtualserverBytesOut(
    String[] names
)
```

getVirtualserverConnectTimedOut(names) throws InvalidInput, InvalidObjectName

Connections closed by this virtual server because the 'connect_timeout' interval was exceeded, for each of the named Virtualservers.

```
Integer[] getVirtualserverConnectTimedOut(
    String[] names
)
```

getVirtualserverConnectionErrors(names)

Number of transaction or protocol errors in this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverConnectionErrors(
    String[] names
)
```

getVirtualserverConnectionFailures(names)

Number of connection failures in this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverConnectionFailures(
   String[] names
)
```

getVirtualserverCurrentConn(names) throws InvalidInput, InvalidObjectName

TCP connections currently established to this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverCurrentConn(
   String[] names
)
```

getVirtualserverDataTimedOut(names) throws InvalidInput, InvalidObjectName

Connections closed by this virtual server because the 'timeout' interval was exceeded, for each of the named Virtualservers.

```
Integer[] getVirtualserverDataTimedOut(
   String[] names
)
```

getVirtualserverDirectReplies(names) throws InvalidInput, InvalidObjectName

Direct replies from this virtual server, without forwarding to a node, for each of the named Virtualservers.

```
Integer[] getVirtualserverDirectReplies(
   String[] names
)
```

getVirtualserverDiscard(names) throws InvalidInput, InvalidObjectName

Connections discarded by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverDiscard(
   String[] names
)
```

getVirtualserverGzip(names) throws InvalidInput, InvalidObjectName

Responses which have been compressed by content compression, for each of the named Virtualservers.

```
Integer[] getVirtualserverGzip(
    String[] names
)
```

getVirtualserverGzipBytesSaved(names) throws InvalidInput, InvalidObjectName

Bytes of network traffic saved by content compression, for each of the named Virtualservers.

```
Long[] getVirtualserverGzipBytesSaved(
    String[] names
)
```

getVirtualserverHttpCacheHitRate(names) throws InvalidInput, InvalidObjectName

Percentage hit rate of the web cache for this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverHttpCacheHitRate(
    String[] names
)
```

getVirtualserverHttpCacheHits(names) throws InvalidInput, InvalidObjectName

HTTP responses sent directly from the web cache by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverHttpCacheHits(
    String[] names
)
```

getVirtualserverHttpCacheLookups(names) throws InvalidInput, InvalidObjectName

HTTP requests that are looked up in the web cache by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverHttpCacheLookups(
    String[] names
)
```

getVirtualserverHttpRewriteCookie(names) throws InvalidInput, InvalidObjectName

HTTP Set-Cookie headers, supplied by a node, that have been rewritten, for each of the named Virtualservers.

```
Integer[] getVirtualserverHttpRewriteCookie(
    String[] names
)
```

getVirtualserverHttpRewriteLocation(names) throws InvalidInput, InvalidObjectName

HTTP Location headers, supplied by a node, that have been rewritten, for each of the named Virtualservers.

```
Integer[] getVirtualserverHttpRewriteLocation(
    String[] names
)
```

getVirtualserverKeepaliveTimedOut(names) throws InvalidInput, InvalidObjectName

Connections closed by this virtual server because the 'keepalive_timeout' interval was exceeded, for each of the named Virtualservers.

```
Integer[] getVirtualserverKeepaliveTimedOut(
    String[] names
)
```

getVirtualserverMaxConn(names) throws InvalidInput, InvalidObjectName

Maximum number of simultaneous TCP connections this virtual server has processed at any one time, for each of the named Virtualservers.

```
Integer[] getVirtualserverMaxConn(
    String[] names
)
```

getVirtualserverNumber()

The number of virtual servers.

```
Integer getVirtualserverNumber()
```

getVirtualserverPort(names) throws InvalidInput, InvalidObjectName

The port the virtual server listens on, for each of the named Virtualservers.

```
Integer[] getVirtualserverPort(
    String[] names
)
```

getVirtualserverProtocol(names) throws InvalidInput, InvalidObjectName

The protocol the virtual server is operating, for each of the named Virtualservers.

```
System.Stats.VirtualserverProtocol[] getVirtualserverProtocol(
    String[] names
)
```

getVirtualserverSIPRejectedRequests(names) throws InvalidInput, InvalidObjectName

Number of SIP requests rejected due to them exceeding the maximum amount of memory allocated to the connection, for each of the named Virtualservers.

```
Integer[] getVirtualserverSIPRejectedRequests(
    String[] names
)
```

getVirtualserverSIPTotalCalls(names) throws InvalidInput, InvalidObjectName

Total number of SIP INVITE requests seen by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverSIPTotalCalls(
    String[] names
)
```

getVirtualserverTotalConn(names) throws InvalidInput, InvalidObjectName

Requests received by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverTotalConn(
    String[] names
)
```

getVirtualserverTotalDgram(names) throws InvalidInput, InvalidObjectName

UDP datagrams processed by this virtual server, for each of the named Virtualservers.

```
Integer[] getVirtualserverTotalDgram(
    String[] names
)
```

getVirtualserverUdpTimedOut(names) throws InvalidInput, InvalidObjectName

Connections closed by this virtual server because the 'udp_timeout' interval was exceeded, for each of the named Virtualservers.

```
Integer[] getVirtualserverUdpTimedOut(
    String[] names
)
```

getVirtualservers()

Gets the list of Virtual Servers configured and enabled.

```
String[] getVirtualservers()
```

getWebCacheEntries()

The number of items in the web cache.

```
Integer getWebCacheEntries()
```

getWebCacheHitRate()

The percentage of web cache lookups that succeeded.

```
Integer getWebCacheHitRate()
```

getWebCacheHits()

Number of times a page has been successfully found in the web cache.

```
Long getWebCacheHits()
```

getWebCacheLookups()

Number of times a page has been looked up in the web cache.

```
Long getWebCacheLookups()
```

getWebCacheMaxEntries()

The maximum number of items in the web cache.

```
Integer getWebCacheMaxEntries()
```

getWebCacheMemMaximum()

The maximum amount of memory the web cache can use in kilobytes.

```
Integer getWebCacheMemMaximum()
```

getWebCacheMemUsed()

Total memory used by the web cache in kilobytes.

```
Integer getWebCacheMemUsed()
```

getWebCacheMisses()

Number of times a page has not been found in the web cache.

```
Long getWebCacheMisses()
```

getWebCacheOldest()

The age of the oldest item in the web cache (in seconds).

```
Integer getWebCacheOldest()
```

getZxtmNumber()

The number of traffic managers in the cluster.

```
Integer getZxtmNumber()
```

6.31.2 Structures

System.Stats.Node

Represents a Node object.

```
struct System.Stats.Node {
    # The IPv4 or IPv6 address of this node.
    String Address;

    # The port this node listens on.
    Integer Port;
}
```

System.Stats.PerLocationService

Represents a PerLocationService object.

```
struct System.Stats.PerLocationService {
```

```
        # The name of the location.
        String LocationName;

        # The name of the GLB Service.
        String Name;
    }
```

System.Stats.PerNodeServiceLevel

Represents a PerNodeServiceLevel object.

```
    struct System.Stats.PerNodeServiceLevel {
        # The name of the SLM class.
        String SLMName;

        # The IP address of this node.
        String NodeAddress;

        # The port number of this node.
        Integer NodePort;
    }
```

System.Stats.PerPoolNode

Represents a PerPoolNode object.

```
    struct System.Stats.PerPoolNode {
        # The name of the pool that this node belongs to.
        String PoolName;

        # The IPv4 or IPv6 address of this node.
        String NodeAddress;

        # The port that this node listens on.
        Integer NodePort;
    }
```

6.31.3 Enumerations

System.Stats.NodeState

```
    enum System.Stats.NodeState {
        alive,

        dead,

        unknown
    }
```

System.Stats.PerLocationServiceDraining

```
enum System.Stats.PerLocationServiceDraining {
   draining,

   active
}
```

System.Stats.PerLocationServiceFrontendState

```
enum System.Stats.PerLocationServiceFrontendState {
   alive,

   dead
}
```

System.Stats.PerLocationServiceMonitorState

```
enum System.Stats.PerLocationServiceMonitorState {
   alive,

   dead
}
```

System.Stats.PerLocationServiceState

```
enum System.Stats.PerLocationServiceState {
   alive,

   dead
}
```

System.Stats.PerPoolNodeState

```
enum System.Stats.PerPoolNodeState {
   alive,

   dead,

   unknown,

   draining
}
```

System.Stats.PoolAlgorithm

```
enum System.Stats.PoolAlgorithm {
   roundrobin,
```

```
        weightedRoundRobin,

        perceptive,

        leastConnections,

        fastestResponseTime,

        random,

        weightedLeastConnections
    }
```

System.Stats.PoolPersistence

```
    enum System.Stats.PoolPersistence {
        none,

        ip,

        rule,

        transparent,

        applicationCookie,

        xZeusBackend,

        ssl
    }
```

System.Stats.PoolState

```
    enum System.Stats.PoolState {
        active,

        disabled,

        draining,

        unused,

        unknown
    }
```

System.Stats.ServiceLevelIsOK

```
    enum System.Stats.ServiceLevelIsOK {
```

```
        notok,

        ok
}
```

System.Stats.TrafficIPState

```
enum System.Stats.TrafficIPState {
    raised,

    lowered
}
```

System.Stats.VirtualserverProtocol

```
enum System.Stats.VirtualserverProtocol {
    http,

    https,

    ftp,

    imaps,

    imapv2,

    imapv3,

    imapv4,

    pop3,

    pop3s,

    smtp,

    ldap,

    ldaps,

    telnet,

    sslforwarding,

    udpstreaming,

    udp,

    dns,
```

```
        genericserverfirst,

        genericclientfirst,

        dnstcp,

        sipudp,

        siptcp,

        rtsp
    }
```

6.32 System.Management

URI: `http://soap.zeus.com/zxtm/1.0/System/Management/`

The System.Management interface provides methods to manage the traffic manager and the system, such as restarting the software.

6.32.1 Methods

rebootSystem()

Perform a system reboot.

```
    void rebootSystem()
```

restartAFM() throws InvalidOperation

Restart the Zeus Application Firewall Module on all machines. Any connections currently using Zeus AFM will be aborted.

```
    void restartAFM()
```

restartJava()

Restart the Java Extension support. Any connections currently using a Java Extension will be aborted.

```
    void restartJava()
```

restartTrafficManager()

Restarts the traffic manager software. Any connections currently being handled will be aborted.

```
    void restartTrafficManager()
```

shutdownSystem()

Perform a system shutdown.

```
void shutdownSystem()
```

6.33 AFM

URI: `http://soap.zeus.com/zxtm/1.0/AFM/`

The AFM interface allows management of the Zeus Application Firewall Module.

6.33.1 Methods

getAdminMasterPort() throws InvalidOperation

Get the Zeus AFM XML Master port, this port is used on all IP addresses.

```
Unsigned Integer getAdminMasterPort()
```

getAdminServerPort() throws InvalidOperation

Get the Zeus AFM Administration server port, this port is used on all IP addresses.

```
Unsigned Integer getAdminServerPort()
```

getAdminServerSessionTimeout() throws InvalidOperation

Get the period of inactivity after which Zeus AFM Administration Server sessions will automatically timeout.

```
Unsigned Integer getAdminServerSessionTimeout()
```

getAdminSlavePort() throws InvalidOperation

Get the Zeus AFM XML Slave port, this port is used on all IP addresses.

```
Unsigned Integer getAdminSlavePort()
```

getClusterState()

Get state data for the Zeus Application Firewall Module across all machines in the cluster.

```
AFM.State[] getClusterState()
```

getDeciderBasePort() throws InvalidOperation

Get the Zeus AFM base decider port. This port, plus one port per decider process above this port, will be used for the Zeus AFM deciders. For example, if set to 8100 then ports 8100, 8101, and 8102 will be used.

```
Unsigned Integer getDeciderBasePort()
```

getInternalDeciderBasePort() throws InvalidOperation

Get the Zeus AFM internal decider communication base port. Zeus AFM requires ports for internal communication, these ports are bound to localhost (127.0.0.1) only. This sets the base for these communication ports, when Zeus AFM is started it will start at this port and work its way up taking available ports until it has enough ports.

```
Unsigned Integer getInternalDeciderBasePort()
```

getNumberOfDeciders() throws InvalidOperation

Get the number of Zeus AFM decider processes to run.

```
Unsigned Integer getNumberOfDeciders()
```

getVersion()

Get the version of the Zeus Application Firewall Module installed on the traffic manager. Returns an empty string if Zeus AFM is not installed.

```
String getVersion()
```

setAdminMasterPort(value) throws InvalidOperation, InvalidInput

Set the Zeus AFM XML Master port, this port is used on all IP addresses.

```
void setAdminMasterPort(
   Unsigned Integer value
)
```

setAdminServerPort(value) throws InvalidOperation, InvalidInput

Set the Zeus AFM Administration server port, this port is used on all IP addresses.

```
void setAdminServerPort(
   Unsigned Integer value
)
```

setAdminServerSessionTimeout(value) throws InvalidOperation, InvalidInput

Set the period of inactivity after which Zeus AFM Administration Server sessions will automatically timeout.

```
void setAdminServerSessionTimeout(
   Unsigned Integer value
)
```

setAdminSlavePort(value) throws InvalidOperation, InvalidInput

Set the Zeus AFM XML Slave port, this port is used on all IP addresses.

```
void setAdminSlavePort(
   Unsigned Integer value
)
```

setDeciderBasePort(value) throws InvalidOperation, InvalidInput

Set the Zeus AFM base decider port. This port, plus one port per decider process above this port, will be used for the Zeus AFM deciders. For example, if set to 8100 then ports 8100, 8101, and 8102 will be used.

```
void setDeciderBasePort(
   Unsigned Integer value
)
```

setInternalDeciderBasePort(value) throws InvalidOperation, InvalidInput

Set the Zeus AFM internal decider communication base port. Zeus AFM requires ports for internal communication, these ports are bound to localhost (127.0.0.1) only. This sets the base for these communication ports, when Zeus AFM is started it will start at this port and work its way up taking available ports until it has enough ports.

```
void setInternalDeciderBasePort(
   Unsigned Integer value
)
```

setNumberOfDeciders(value) throws InvalidOperation, InvalidInput

Set the number of Zeus AFM decider processes to run.

```
void setNumberOfDeciders(
   Unsigned Integer value
)
```

uninstall() throws InvalidOperation

Uninstalls the Zeus Application Firewall Module on the traffic manager.

```
        void uninstall()
```

6.33.2 Structures

AFM.BasicStatus

Contains basic Zeus AFM runtime status information.

```
struct AFM.BasicStatus {
    # Whether or not Zeus AFM is installed.
    String installed;

    # Whether or not Zeus AFM is running.
    String running;

    # The version of Zeus AFM installed.
    String version;

    # Whether or not the maching is clustered with the local Zeus
    # AFM.
    String clustered;
}
```

AFM.ClusterStatus

Contains a Zeus AFM state message.

```
struct AFM.ClusterStatus {
    # Cluster member this status is for.
    String member;

    # Status of the cluster member.
    String status;
}
```

AFM.State

Contains status information about a Zeus AFM installation.

```
struct AFM.State {
    # Name of the machine this information is from.
    String machine;

    # Describes the basic runtime status of Zeus AFM on a machine.
    AFM.BasicStatus basicstatus;

    # State messages from the Zeus AFM on the machine.
    AFM.StateMessage[] messages;

    # Statuses for all AFMs in the AFM's cluster.
```

```
   AFM.ClusterStatus[] messages;

   # Strings describing any general errors relating to Zeus AFM.
   String[] errors;
}
```

AFM.StateMessage

Contains a Zeus AFM state message.

```
struct AFM.StateMessage {
   # State for this message, either OK or ERROR.
   String state;

   # Message describing the reason for the state.
   String message;
}
```

6.34 Location

URI: http://soap.zeus.com/zxtm/1.0/Location/

The Location interface allows management of traffic manager locations. Using this interface, you can create, delete and rename Locations, and manage their configuration.

6.34.1 Methods

addLocation(locations, info) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, InvalidInput, DeploymentError, LicenseError

Adds a Locations. Configuration for the new location will be based on the

```
void addLocation(
   String[] locations
   Location.TypeInfo[] info
)
```

deleteLocation(locations) throws ObjectDoesNotExist, ObjectInUse, DeploymentError, LicenseError

Delete the named Location.

```
void deleteLocation(
   String[] locations
)
```

getCoordinates(locations) throws ObjectDoesNotExist, LicenseError

Get the coordinates for the named locations.

```
Location.Coordinates[] getCoordinates(
   String[] locations
)
```

getLocations()

Get the names of all the configured locations.

```
String[] getLocations()
```

getNote(locations) throws ObjectDoesNotExist, LicenseError

Get the note for each of the named locations

```
String[] getNote(
   String[] locations
)
```

getTrafficManagerLocation(traffic_managers) throws ObjectDoesNotExist, LicenseError

Gets the location that the named traffic managers are in.

```
String[] getTrafficManagerLocation(
   String[] traffic_managers
)
```

getType(locations) throws ObjectDoesNotExist, LicenseError

Gets a location's type, either config or glb. GLB locations contain no traffic managers, and are only used for global load balancing.

```
String[] getType(
   String[] locations
)
```

renameLocation(locations, new_names) throws ObjectDoesNotExist, ObjectAlreadyExists, InvalidObjectName, DeploymentError, LicenseError

Rename the named Locations.

```
void renameLocation(
   String[] locations
   String[] new_names
)
```

setCoordinates(locations, coordinates) throws ObjectDoesNotExist, DeploymentError, LicenseError

Set the coordinates for the named locations. Coordinates are only needed for global load balancing.

```
void setCoordinates(
   String[] locations
   Location.Coordinates[] coordinates
)
```

setNote(locations, values) throws ObjectDoesNotExist, DeploymentError, LicenseError

Set the note for each of the named locations

```
void setNote(
   String[] locations
   String[] values
)
```

setTrafficManagerLocation(traffic_managers, locations) throws ObjectDoesNotExist, LicenseError, DeploymentError

Sets the location that the named traffic managers are in.

```
void setTrafficManagerLocation(
   String[] traffic_managers
   String[] locations
)
```

setType(locations, type_info) throws ObjectInUse, ObjectDoesNotExist, LicenseError, InvalidInput

Sets a location's type, either config or glb. GLB locations contain no traffic managers, and are only used for global load balancing.

```
void setType(
   String[] locations
   Location.TypeInfo[] type_info
)
```

6.34.2 Structures

Location.Coordinates

This structure contains the co-ordinates for a location.

```
struct Location.Coordinates {
    # The longitude of the location.
    Double longitude;

    # The latitude of the location.
    Double latitude;
}
```

Location.TypeInfo

This structure contains information required when adding a location.

```
struct Location.TypeInfo {
    # Location type, either config or glb. GLB locations don't
    # contain any traffic managers and are used for global load
    # balancing.
    String type;

    # If the location isn't of type GLB, this is the location that
    # the configuration will be be based on initially
    String based_on;
}
```

6.35 Users

URI: http://soap.zeus.com/zxtm/1.0/Users/

The Users interface allows management of users of Zeus Traffic Manager. Using this interface, you can create and delete users, assign them to permission groups and manage their configuration.

6.35.1 Methods

addUser(user, password, group) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidInput

Add a new local user to Zeus Traffic Manager.

```
void addUser(
    String user
    String password
    String group
)
```

changePassword(user, newPassword) throws ObjectDoesNotExist

Change password for a given user.

```
void changePassword(
   String user
   String newPassword
)
```

deleteUser(user) throws ObjectDoesNotExist, DeploymentError

Delete a local user from Zeus Traffic Manager.

```
void deleteUser(
   String user
)
```

listGroups()

List all groups of Zeus Traffic Manager.

```
String[] listGroups()
```

listUsers()

List all users of Zeus Traffic Manager.

```
String[] listUsers()
```

6.36 GLB.Service

URI: `http://soap.zeus.com/zxtm/1.0/GLB/Service/`

The GLB.Service interface allows management of Global Load Balancing Services. Using this interface, you can create, delete and rename pool objects, and manage their configuration.

6.36.1 Methods

addDNSSECMappings(names, mappings) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add a set of DNSSEC domain to key mappings to the GLB services specified.

```
void addDNSSECMappings(
   String[] names
   GLB.Service.DNSSECMapping[][] mappings
```

)

addDomains(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

For each named GLB service, add new DNS domain names to the list of domains to load balance

```
void addDomains(
   String[] names
   String[][] values
)
```

addDraining(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add the list of locations that are draining for this service.

```
void addDraining(
   String[] names
   String[][] values
)
```

addGLBService(names, domains) throws ObjectAlreadyExists, InvalidObjectName, DeploymentError, InvalidInput, LicenseError

Add each of the named GLB Services, using the domain lists for each.

```
void addGLBService(
   String[] names
   String[][] domains
)
```

addLocalIPAddresses(names, localips) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add Local IPs to the named GLB Services

```
void addLocalIPAddresses(
   String[] names
   GLB.Service.LocalIPList[][] localips
)
```

addLocations(names, locations) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add new locations to each of the named GLB services.

```
void addLocations(
    String[] names
    String[][] locations
)
```

addMonitors(names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add Monitors to the named GLB Services

```
void addMonitors(
    String[] names
    GLB.Service.MonitorList[][] monitors
)
```

addMonitorsByLocation(location, names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add Monitors to the named GLB Services This is a location specific function, any action will operate on the specified location.

```
void addMonitorsByLocation(
    String location
    String[] names
    GLB.Service.MonitorList[][] monitors
)
```

addRules(names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add new rules to be run on DNS packets for each of the named GLB services. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in.

```
void addRules(
    String[] names
    GLB.Service.Rule[][] rules
)
```

addRulesByLocation(location, names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Add new rules to be run on DNS packets for each of the named GLB services. New rules are run after existing rules. If any of the rules are already configured to run, then they are enabled and flags are set to the values passed in. This is a location specific function, any action will operate on the specified location.

```
void addRulesByLocation(
```

```
        String location
        String[] names
        GLB.Service.Rule[][] rules
    )
```

deleteGLBService(names) throws ObjectDoesNotExist, DeploymentError

Delete each of the named GLB Services.

```
    void deleteGLBService(
        String[] names
    )
```

getAlgorithm(names) throws ObjectDoesNotExist, LicenseError

Get the load balancing algorithm to use.

```
    GLB.Service.Algorithm[] getAlgorithm(
        String[] names
    )
```

getAllMonitorsNeeded(names) throws ObjectDoesNotExist, LicenseError

Get whether all monitors are required to be working in a location for this service to be alive.

```
    Boolean[] getAllMonitorsNeeded(
        String[] names
    )
```

getAutoFailback(names) throws ObjectDoesNotExist, LicenseError

Get whether automatic failback mode is enabled.

```
    Boolean[] getAutoFailback(
        String[] names
    )
```

getDNSSECMappings(names) throws ObjectDoesNotExist, LicenseError

Get the load for the named GLB Services

```
    GLB.Service.DNSSECMapping[][] getDNSSECMappings(
        String[] names
    )
```

getDomains(names) throws ObjectDoesNotExist, LicenseError

Get the list of domain names to load balance, for each of the named GLB services

```
String[][] getDomains(
   String[] names
)
```

getDraining(names) throws ObjectDoesNotExist, LicenseError

Get the list of locations that are draining for this service.

```
String[][] getDraining(
   String[] names
)
```

getEnabled(names) throws ObjectDoesNotExist, LicenseError

Get whether we perform DNS manipulation.

```
Boolean[] getEnabled(
   String[] names
)
```

getGLBServiceNames()

Get the names of all of the configured GLB Services.

```
String[] getGLBServiceNames()
```

getGeoEffect(names) throws ObjectDoesNotExist, LicenseError

Get the influence of locality on location choice

```
Unsigned Integer[] getGeoEffect(
   String[] names
)
```

getLoad(names) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Get the load for the named GLB Services

```
GLB.Service.Load[][] getLoad(
   String[] names
)
```

getLocalIPAddresses(names) throws ObjectDoesNotExist, LicenseError

Get the Local IPs configured for the named GLB Services

```
GLB.Service.LocalIPList[][] getLocalIPAddresses(
   String[] names
)
```

getLocations(names) throws ObjectDoesNotExist, LicenseError

Get the locations configured for the named GLB services.

```
String[][] getLocations(
   String[] names
)
```

getLogEnabled(names) throws ObjectDoesNotExist, LicenseError

Get whether each of the named GLB services should log each connection.

```
Boolean[] getLogEnabled(
   String[] names
)
```

getLogEnabledByLocation(location, names) throws ObjectDoesNotExist, LicenseError

Get whether each of the named GLB services should log each connection. This is a location specific function, any action will operate on the specified location.

```
Boolean[] getLogEnabledByLocation(
   String location
   String[] names
)
```

getLogFilename(names) throws ObjectDoesNotExist, LicenseError

Get the name of the file used to store query logs, for each of the named GLB services.

```
String[] getLogFilename(
   String[] names
)
```

getLogFilenameByLocation(location, names) throws ObjectDoesNotExist, LicenseError

Get the name of the file used to store query logs, for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
String[] getLogFilenameByLocation(
   String location
   String[] names
)
```

getLogFormat(names) throws ObjectDoesNotExist, LicenseError

Get the log file format for each of the named GLB services.

```
String[] getLogFormat(
   String[] names
)
```

getLogFormatByLocation(location, names) throws ObjectDoesNotExist, LicenseError

Get the log file format for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
String[] getLogFormatByLocation(
   String location
   String[] names
)
```

getMonitors(names) throws ObjectDoesNotExist, LicenseError

Get the Monitors configured for the named GLB Services

```
GLB.Service.MonitorList[][] getMonitors(
   String[] names
)
```

getMonitorsByLocation(location, names) throws ObjectDoesNotExist, LicenseError

Get the Monitors configured for the named GLB Services This is a location specific function, any action will operate on the specified location.

```
GLB.Service.MonitorList[][] getMonitorsByLocation(
   String location
   String[] names
)
```

getReturnIPsOnFail(names) throws ObjectDoesNotExist, LicenseError

Get whether to return all or no IP addresses on a complete failure

```
Boolean[] getReturnIPsOnFail(
```

```
        String[] names
    )
```

getRules(names) throws ObjectDoesNotExist, LicenseError

Get the rules that are run on DNS packets for each of the named GLB services.

```
    GLB.Service.Rule[][] getRules(
        String[] names
    )
```

getRulesByLocation(location, names) throws ObjectDoesNotExist, LicenseError

Get the rules that are run on DNS packets for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
    GLB.Service.Rule[][] getRulesByLocation(
        String location
        String[] names
    )
```

getTTL(names) throws ObjectDoesNotExist, LicenseError

Get the TTL used for domains handled by this config

```
    Integer[] getTTL(
        String[] names
    )
```

removeDNSSECMappings(names, mappings) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Remove the specified DNSSEC domain to key mappings.

```
    void removeDNSSECMappings(
        String[] names
        GLB.Service.DNSSECMapping[][] mappings
    )
```

removeDomains(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

For each named GLB service, remove DNS domain names from the list of domains to load balance

```
    void removeDomains(
        String[] names
```

```
         String[][] values
    )
```

removeDraining(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Remove the list of locations that are draining for this service.

```
void removeDraining(
    String[] names
    String[][] values
)
```

removeLocalIPAddresses(names, localips) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Remove Local IPs from the named GLB Services

```
void removeLocalIPAddresses(
    String[] names
    GLB.Service.LocalIPList[][] localips
)
```

removeLocations(names, locations) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

For each of the named GLB services, remove locations.

```
void removeLocations(
    String[] names
    String[][] locations
)
```

removeMonitors(names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Remove Monitors from the named GLB Services

```
void removeMonitors(
    String[] names
    GLB.Service.MonitorList[][] monitors
)
```

removeMonitorsByLocation(location, names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Remove Monitors from the named GLB Services This is a location specific function, any action will operate on the specified location.

```
void removeMonitorsByLocation(
    String location
    String[] names
    GLB.Service.MonitorList[][] monitors
)
```

removeRules(names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

For each of the named GLB services, remove rules from the list of rules that are run on DNS packets.

```
void removeRules(
    String[] names
    String[][] rules
)
```

removeRulesByLocation(location, names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

For each of the named GLB services, remove rules from the list of rules that are run on DNS packets. This is a location specific function, any action will operate on the specified location.

```
void removeRulesByLocation(
    String location
    String[] names
    String[][] rules
)
```

renameGLBService(names, new_names) throws ObjectDoesNotExist, InvalidInput, ObjectAlreadyExists, DeploymentError, LicenseError

Rename each of the named GLB Services.

```
void renameGLBService(
    String[] names
    String[] new_names
)
```

setAlgorithm(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the load balancing algorithm to use.

```
void setAlgorithm(
   String[] names
   GLB.Service.Algorithm[] values
)
```

setAllMonitorsNeeded(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether all monitors are required to be working in a location for this service to be alive.

```
void setAllMonitorsNeeded(
   String[] names
   Boolean[] values
)
```

setAutoFailback(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether automatic failback mode is enabled.

```
void setAutoFailback(
   String[] names
   Boolean[] values
)
```

setDNSSECMappings(names, mappings) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the DNSSEC domain to key mappings to the GLB services specified. All previous mappings for this service will be removed.

```
void setDNSSECMappings(
   String[] names
   GLB.Service.DNSSECMapping[][] mappings
)
```

setDomains(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the list of domain names to load balance, for each of the named GLB services

```
void setDomains(
   String[] names
```

```
    String[][] values
)
```

setDraining(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the list of locations that are draining for this service.

```
void setDraining(
    String[] names
    String[][] values
)
```

setEnabled(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether we perform DNS manipulation.

```
void setEnabled(
    String[] names
    Boolean[] values
)
```

setGeoEffect(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the influence of locality on location choice

```
void setGeoEffect(
    String[] names
    Unsigned Integer[] values
)
```

setLoad(names, loads) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the load for the named GLB Services

```
void setLoad(
    String[] names
    GLB.Service.Load[][] loads
)
```

setLocalIPAddresses(names, localips) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the Local IPs configured for the named GLB Services

```
void setLocalIPAddresses(
   String[] names
   GLB.Service.LocalIPList[][] localips
)
```

setLocations(names, locations) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the locations configured for each of the named GLB services.

```
void setLocations(
   String[] names
   String[][] locations
)
```

setLogEnabled(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether each of the named GLB services should log each connection.

```
void setLogEnabled(
   String[] names
   Boolean[] values
)
```

setLogEnabledByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether each of the named GLB services should log each connection. This is a location specific function, any action will operate on the specified location.

```
void setLogEnabledByLocation(
   String location
   String[] names
   Boolean[] values
)
```

setLogFilename(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the name of the file used to store query logs, for each of the named GLB services.

```
void setLogFilename(
   String[] names
   String[] values
)
```

setLogFilenameByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the name of the file used to store query logs, for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
void setLogFilenameByLocation(
   String location
   String[] names
   String[] values
)
```

setLogFormat(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the log file format for each of the named GLB services.

```
void setLogFormat(
   String[] names
   String[] values
)
```

setLogFormatByLocation(location, names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the log file format for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
void setLogFormatByLocation(
   String location
   String[] names
   String[] values
)
```

setMonitors(names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the Monitors configured for the named GLB Services

```
void setMonitors(
   String[] names
   GLB.Service.MonitorList[][] monitors
)
```

setMonitorsByLocation(location, names, monitors) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the Monitors configured for the named GLB Services This is a location specific function, any action will operate on the specified location.

```
void setMonitorsByLocation(
   String location
   String[] names
   GLB.Service.MonitorList[][] monitors
)
```

setReturnIPsOnFail(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set whether to return all or no IP addresses on a complete failure

```
void setReturnIPsOnFail(
   String[] names
   Boolean[] values
)
```

setRules(names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the rules that are run on DNS packets for each of the named GLB services.

```
void setRules(
   String[] names
   GLB.Service.Rule[][] rules
)
```

setRulesByLocation(location, names, rules) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the rules that are run on DNS packets for each of the named GLB services. This is a location specific function, any action will operate on the specified location.

```
void setRulesByLocation(
   String location
   String[] names
   GLB.Service.Rule[][] rules
)
```

setTTL(names, values) throws ObjectDoesNotExist, InvalidInput, DeploymentError, LicenseError

Set the TTL used for domains handled by this config

```
void setTTL(
    String[] names
    Integer[] values
)
```

6.36.2 Structures

GLB.Service.DNSSECMapping

This contains a mapping between DNS domains and DNSSEC keys used to alter signed responses.

```
struct GLB.Service.DNSSECMapping {
    # The domain of these keys sign.
    String domain;

    # An array of DNSSEC key names.
    String[] keys;
}
```

GLB.Service.Load

This structure contains the load for a GLB location.

```
struct GLB.Service.Load {
    # The glb location.
    String location;

    # The load metric at the corresponding location.
    Integer load;
}
```

GLB.Service.LocalIPList

This structure contains the list of IP addresses for a GLB location.

```
struct GLB.Service.LocalIPList {
    # The glb location.
    String location;

    # The IP Addresses or IP Masks that are present at the
    # corresponding location.
    String[] addresses;
}
```

GLB.Service.MonitorList

This structure contains the list of monitors for a GLB location.

```
struct GLB.Service.MonitorList {
    # The glb location.
    String location;

    # The monitors determining the health of the corresponding
    # location.
    String[] monitors;
}
```

GLB.Service.Rule

This structure contains the information on how a rule is assigned to a virtual server.

```
struct GLB.Service.Rule {
    # The name of the rule.
    String name;

    # Whether the rule is enabled or not.
    Boolean enabled;
}
```

6.36.3 Enumerations

GLB.Service.Algorithm

```
enum GLB.Service.Algorithm {
    # Load
    load,

    # Geographic
    geo,

    # Adaptive
    hybrid,

    # Round Robin
    roundrobin,

    # Weighted Random
    weightedrandom,

    # Active/Passive
    chained
}
```

6.37 System.CloudCredentials

URI: http://soap.zeus.com/zxtm/1.0/System/CloudCredentials/

The System.CloudCredentials interface allows management of Cloud Credentials. Using this interface, you can create, delete and rename sets of cloud credentials, and manage their configuration.

6.37.1 Methods

addCloudCredentials(class_names, class_values) throws ObjectAlreadyExists, InvalidInput

Add new sets of cloud credentials.

```
void addCloudCredentials(
   String[] class_names
   System.CloudCredentials.CredentialsData[] class_values
)
```

copyCloudCredentials(class_names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError

Copy the named set of cloud credentials.

```
void copyCloudCredentials(
   String[] class_names
   String[] new_names
)
```

deleteCloudCredentials(class_names) throws ObjectDoesNotExist, DeploymentError

Delete the named sets of cloud credentials.

```
void deleteCloudCredentials(
   String[] class_names
)
```

getCloudCredentialsNames()

Get the names of all the configured cloud credentials.

```
String[] getCloudCredentialsNames()
```

getCred1(class_names) throws ObjectDoesNotExist

Get the cloud user name

```
String[] getCred1(
   String[] class_names
)
```

getCred1ByLocation(location, class_names) throws ObjectDoesNotExist

Get the cloud user name This is a location specific function, any action will operate on the specified location.

```
String[] getCred1ByLocation(
   String location
   String[] class_names
)
```

getScript(class_names) throws ObjectDoesNotExist

Get the script

```
String[] getScript(
   String[] class_names
)
```

getScriptByLocation(location, class_names) throws ObjectDoesNotExist

Get the script This is a location specific function, any action will operate on the specified location.

```
String[] getScriptByLocation(
   String location
   String[] class_names
)
```

getUpdateInterval(class_names) throws ObjectDoesNotExist

Get the interval at which cloud status is queried

```
Unsigned Integer[] getUpdateInterval(
   String[] class_names
)
```

getUpdateIntervalByLocation(location, class_names) throws ObjectDoesNotExist

Get the interval at which cloud status is queried This is a location specific function, any action will operate on the specified location.

```
Unsigned Integer[] getUpdateIntervalByLocation(
   String location
   String[] class_names
)
```

renameCloudCredentials(class_names, new_names) throws ObjectAlreadyExists, ObjectDoesNotExist, InvalidObjectName, DeploymentError

Rename the named sets of cloud credentials.

```
void renameCloudCredentials(
   String[] class_names
   String[] new_names
)
```

setCred1(class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user name

```
void setCred1(
   String[] class_names
   String[] values
)
```

setCred1ByLocation(location, class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user name This is a location specific function, any action will operate on the specified location.

```
void setCred1ByLocation(
   String location
   String[] class_names
   String[] values
)
```

setCred2(class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user password

```
void setCred2(
   String[] class_names
   String[] values
)
```

setCred2ByLocation(location, class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user password This is a location specific function, any action will operate on the specified location.

```
void setCred2ByLocation(
   String location
   String[] class_names
   String[] values
)
```

setCred3(class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user authentication token

```
void setCred3(
   String[] class_names
   String[] values
)
```

setCred3ByLocation(location, class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the cloud user authentication token This is a location specific function, any action will operate on the specified location.

```
void setCred3ByLocation(
   String location
   String[] class_names
   String[] values
)
```

setScript(class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the script

```
void setScript(
   String[] class_names
   String[] values
)
```

setScriptByLocation(location, class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the script This is a location specific function, any action will operate on the specified location.

```
void setScriptByLocation(
   String location
   String[] class_names
   String[] values
```

```
)
```

setUpdateInterval(class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the interval at which cloud status is queried

```
void setUpdateInterval(
   String[] class_names
   Unsigned Integer[] values
)
```

setUpdateIntervalByLocation(location, class_names, values) throws InvalidInput, ObjectDoesNotExist, DeploymentError

Set the interval at which cloud status is queried This is a location specific function, any action will operate on the specified location.

```
void setUpdateIntervalByLocation(
   String location
   String[] class_names
   Unsigned Integer[] values
)
```

6.37.2 Structures

System.CloudCredentials.CredentialsData

This structure contains the information needed to create CloudCredentials

```
struct System.CloudCredentials.CredentialsData {
   # The user name (mandatory)
   String cred1;

   # The password (mandatory)
   String cred2;

   # The authorization token (can be empty)
   String cred3;

   # The script to use for API calls (mandatory)
   String script;

   # Time period to wait between status API calls in seconds
   Integer update_interval;
}
```

6.38 SOAP Faults

When a function encounters an error it will emit a fault. Depending on the fault that occurred the fault structure will contain more information related to the fault. The documentation for individual functions lists the different types of faults that a function can emit.

6.38.1 Faults

DeploymentError

The DeploymentError fault is raised when a configuration change causes errors when attempting to apply the configuration to a running traffic manager. It would be raised in cases such as failing to bind to a port when enabling a Virtual Server.

```
struct DeploymentError {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault (if
    # appropriate)
    String object;

    # The configuration key that caused the fault (if appropriate)
    String key;

    # The value that caused the fault (if appropriate)
    String value;
}
```

InvalidInput

The InvalidInput fault is raised when the input to a function is invalid, for example a number was out of range. This fault is also raised in cases such as VirtualServer.setPool() where the Pool doesn't exist The details in the fault contain the object, key and value that caused the fault. These might be blank if they are not relevant to the fault.

```
struct InvalidInput {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault (if
    # appropriate)
    String object;

    # The configuration key that caused the fault (if appropriate)
    String key;

    # The value that caused the fault (if appropriate)
    String value;
```

```
    }
```

InvalidObjectName

The InvalidObjectName fault is raised when attempting to create a new object (e.g. via an add, rename or copy) and the name is invalid (e.g. it contains a '/').

```
struct InvalidObjectName {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault
    String object;
}
```

InvalidOperation

The InvalidOperation fault is emitted when attempting an operation that doesn't make sense or is prohibited, for example deleting a built-in monitor, or attempting to rename an object twice in the same call.

```
struct InvalidOperation {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault (if
    # appropriate)
    String object;

    # The configuration key that caused the fault (if appropriate)
    String key;

    # The value that caused the fault (if appropriate)
    String value;
}
```

LicenseError

The LicenseError fault is emitted when attempting to use functionality that is disabled by the license key. You will need to contact your support provider to get a new license key with the required functionality. There may be a charge for this.

```
struct LicenseError {
    # A human readable string describing the error
    String errmsg;

    # The license key feature that was missing
    String feature;
}
```

ObjectAlreadyExists

The ObjectAlreadyExists fault is raised when attempting to create an object (such as a Virtual Server) that already exists. It will also be raised in cases such as renaming and copying objects.

```
struct ObjectAlreadyExists {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault
    String object;
}
```

ObjectDoesNotExist

The ObjectDoesNotExist fault is raised when attempting to perform an operation on an object (such as Virtual Server) that doesn't exist. This fault will only be raised if the primary object in the call doesn't exist. For example if calling VirtualServer.setPool(), then this fault will be raised if the Virtual Server doesn't exist, but if the Pool doesn't exist then the "InvalidInput" fault will be raised.

```
struct ObjectDoesNotExist {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault
    String object;
}
```

ObjectInUse

The ObjectInUse fault is raised when attempting to delete an object that is referenced by another object, for example deleting a Pool that is in use by a Virtual Server.

```
struct ObjectInUse {
    # A human readable string describing the error
    String errmsg;

    # The name of the object that caused the fault
    String object;
}
```

Further Information

7.1   Zeus Manuals

Bundled with the software is a Getting Started Guide, intended to get you up and running quickly with the software. If you have purchased a Zeus Appliance, you will also find a specific Appliance Quick-Start guide which you should read before installing and configuring the appliance for the first time. There is also a full User Guide, and a manual for the TrafficScript rules language.

You can access these manuals via the **Help** pages (described below), or download the most recent versions from the Zeus KnowledgeHub at http://knowledgehub.zeus.com/.

7.2   Information online

Product specifications can be found at:

http://www.zeus.com/products/

Visit Zeus KnowledgeHub for further documentation, examples, white papers and other resources:
